1. Purpose of Document

This report has been prepared for Barwon Water and is intended to accompany a heritage permit application for a new project involving demolition of all spans of the heritage listed Ovoid Sewer Aqueduct over the Barwon River ('the Aqueduct').

This application for demolition follows an extensive period of condition reporting, structural engineering studies, constructability reviews, and risk assessments that have been undertaken by Barwon Water, Arup and the project team between 2019-2025, in the pursuit of reopening the Barwon River and seeking a safely constructible solution for the scope of works outlined in the 2020 heritage permit P32806 (namely partial demolition of the 4x river spans, and conservation works to the remainder of the structure).

The report is to be read in conjunction with the following documents:

- Lovell Chen: Heritage Impact Statement (August 2025)
- Lovell Chen/Arup: Heritage Infrastructure Management Plan Part 1 (2022)
- Arup: Barwon River Ovoid Sewer Aqueduct Demolition Works Drawings (P1 issue, 07/07/2025, 5 sheets)

2. Executive Summary

The studies and assessments undertaken on the aqueduct over the past five years have yielded a substantial body of knowledge regarding technical aspects of the existing structure, including its current condition, structural behaviour and potential failure modes. This has in turn informed significant safety limitations regarding any works in the vicinity of the structure, which have formed a brief for design of interventions to the structure.

In short, any interventions that require people working near the aqueduct are governed by significant safety risks during construction.

A range of key intervention categories were considered as part the work leading up to and after issue of the 2020 Heritage Permit P32806. These are introduced here, and expanded upon within the report body.

1. **Structural Propping:**

- The partial demolition scope outlined in the 2020 permit required propping to be installed under at least three of the retained spans of the aqueduct, to avoid inducing instability from 'seesaw' action during structural separation.
- The installation of propping under all aqueduct spans can additionally serve to mitigate against a catastrophic 'chain reaction' failure event.
- Propping does not arrest degradation of the structural fabric, which would continue unabated until the eventual failure of the structure.
- Propping underwent significant design, focussing on safety risks to workers during the installation. Any propping scheme comes with safety risks during construction that ultimately cannot be satisfactorily mitigated.
- It is not feasible to undertake maintenance on the propping structures due to safety risks. The propping structures will eventually degrade, noting the 1991 propping structure has not been maintained since it was installed.

2. **Do Nothing**

- The structure in its current state presents a significant public safety risk. A 'do nothing' approach does not address the key project outcome of opening the Barwon River and will result in an eventual uncontained structural collapse at some point in the future. As long as the structure remains standing, the public safety risk remains.

3. **Concrete Repair:**

- Following review with specialists early in the project lifecycle, it was deemed unfeasible to undertake any patch repairs, member recasting or other conservation works directly to the aqueduct structure, due to the safety risks posed for personnel required near the structure and the lack of efficacy of such methods due to the heavily degraded concrete condition.

4. **Demolition**

- The heritage permit P32806 accepted a partial demolition of the structure (4x river spans), in response to the public safety risks and lack of feasible alternative interventions for these spans.
- Following substantial assessment and review, the current proposal for demolition of all superstructure spans is deemed to be the only technically feasible option available that addresses the existing public safety risk profile, whilst not putting construction workers at undue risk during the works.
- The retention of pier bases and stairs as placemaking features is feasible after safe removal of the demolished structure, and allows footprint elements of the structure to be retained on the site as permanent markers.

This report expands upon and addresses the history of these interventions, along with a summary of the aqueduct's structural behaviour, and existing conditions found during condition survey work.

3. Project Background

The Barwon Sewer Aqueduct, constructed between 1913 and 1916, is a heritage-listed reinforced concrete truss structure spanning the Barwon River near Breakwater, Victoria. The bridge is approximately 750m in length and comprises 14 interconnected spans. The aqueduct originally served to carry a gravity sewer pipe across the Barwon River and floodplain but was decommissioned in the early 1990's and now no longer serves a practical purpose.

The aqueduct was a pioneering feat of engineering at the time and remains of significant historical, architectural, and technical value – this was recognised in its heritage listing at the time of its decommissioning.

The structure has suffered significant decay, largely due to its unique reinforced concrete truss structural form and the relatively low-quality concrete comprising its primary structural elements. A significant number of repairs on the structure have been documented throughout its service life, from soon after construction up until its decommissioning. At decommissioning, the structure was already in poor condition, with propping being installed under Span 14. Since decommissioning, the structure has not had any recorded repairs, other than corrosion repair trials undertaken in 2009.

At inception of the current project in 2019, the area under the structure, including the Barwon River, had already been closed to the public for some time, due to safety risks posed by falling concrete and structural failure.

A key driver for the current project was to safely reopen the Barwon River and mitigate the risks to the public that are currently posed by the structure, whilst aiming to retain and conserve as much of the structure as possible. After testing a range of concept options in 2019, a partial demolition of the structure over the river spans was proposed, and a heritage permit issued in 2020 for this scope of works, coupled with conservation of the retained spans.

Since issue of the heritage permit, the project team has undertaken many detailed assessments and design iterations to attempt to satisfy the permit conditions. A history of the design iterations and features are presented within this report, along with commentary as to the outcomes and limitations faced due to the existing structural condition.

4. Structural Behaviour – Summary

A summary of the structural behaviour of the existing aqueduct is provided as background, given the criticality of the structure's behaviour when developing interventions and separation strategies, particularly when considering safety aspects.

4.1 Analysis Methods and Failure Prediction

In a typical situation, the process to predict behaviour of an existing structure involves gathering data on the existing materials and geometry, then undertaking numerical structural analysis to determine the factor of safety against failure. However, the heavily degraded nature of the aqueduct structure (refer Section 5 for full details) makes this type of structural analysis unreliable.

The level of internal degradation, particularly of the reinforcement and its anchorages is the principal unknown, but additionally there are many members of the structure which have been remediated in the past. These remediations do not have documentation available, thus it is not possible to ascertain all of the exact construction details of the structure.

Arup have undertaken a substantial amount of numerical modelling work on the structure, however due to the unknowns, this is not the only tool used for predicting future behaviour of the aqueduct structure. Failure mode identification and analysis is the primary tool used to identify and develop risks and assess efficacy of interventions for this project.

4.2 Balanced Cantilever Structure

Fundamentally, each pier and truss pair and of the aqueduct acts as a balanced cantilever, with the weight of the interconnecting walkway girders and pipe spans acting as loads on the truss tips. These loads are roughly equal so there is no net overturning experienced at the pier tower, analogous to a balanced seesaw. The situation is visually described in Figure 1.

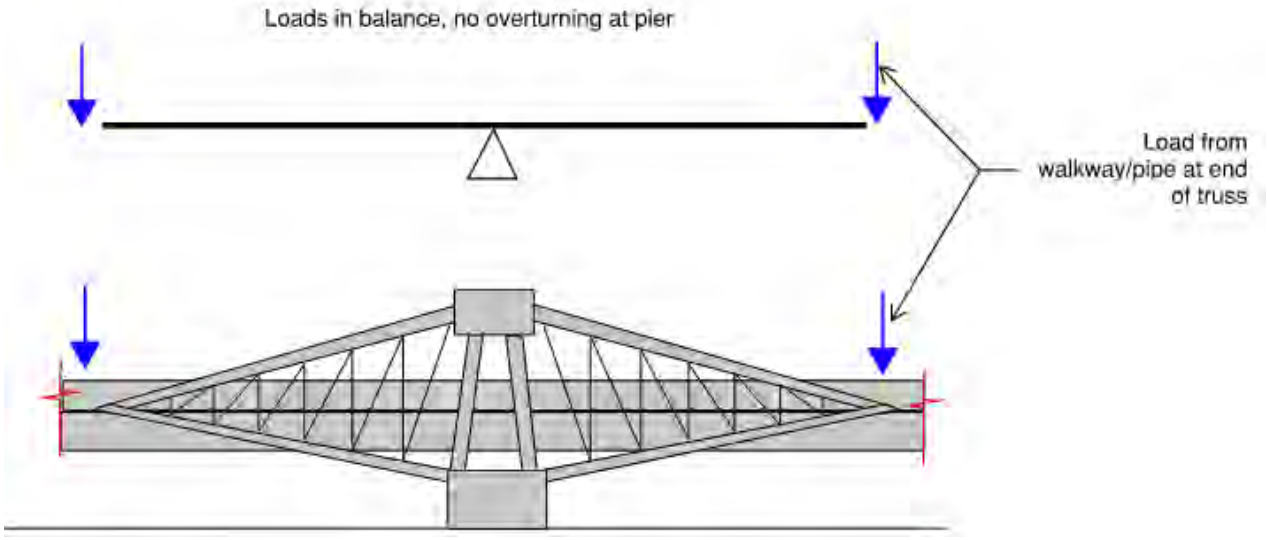

Figure 1 Balanced Cantilever - Seesaw Analogy

This behaviour is important when considering any proposed structural separation, because separating the structure involves a change in the loading regime. Figure 2 shows the potential situation at the separation end if the structure is unpropped, where the removal of load on the end pier could lead to a failure. This is the fundamental reason why propping is required in order to effectively separate the structure.

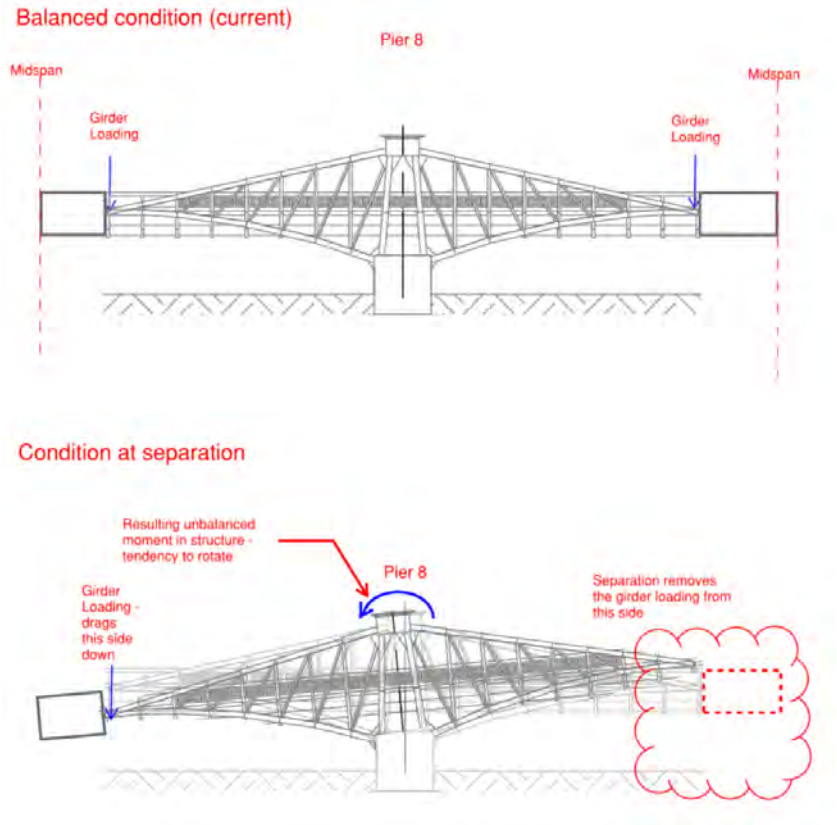

Figure 2 Separation of Structure

4.3 Span Failure

The structure has a low degree of redundancy, particularly in its trusses, thus single failure of the truss or tower can relatively easily lead to a more widespread collapse of the span, and beyond.

Span failure can arise from two basic causes:

1. Disturbance in the balanced loads as already illustrated in Figure 2 (i.e. removal of the walkway/pipe at end of truss ahead of separation)
2. Failure within the structure of the truss/tower system (i.e. single point member failure)

If either of these events occur, then the 'seesaw' has the potential to lose equilibrium, resulting in a collapse of the span. The sequence of collapse is described below and graphically in Figure 3:

1. A single member fails within a truss (Figure 3 top image) – or loading imbalance occurs
2. Load redistribution within the truss occurs, due to the failed member no longer carrying load.
3. The load redistribution causes other members in the truss to become overloaded and fail, in turn causing the entire truss span to fail. The failure deforms the tip of the truss downward (Figure 3 middle image).
4. The pier becomes unbalanced, causing a failure leading to the truss on the opposite side of the pier falling (Figure 3 bottom image).

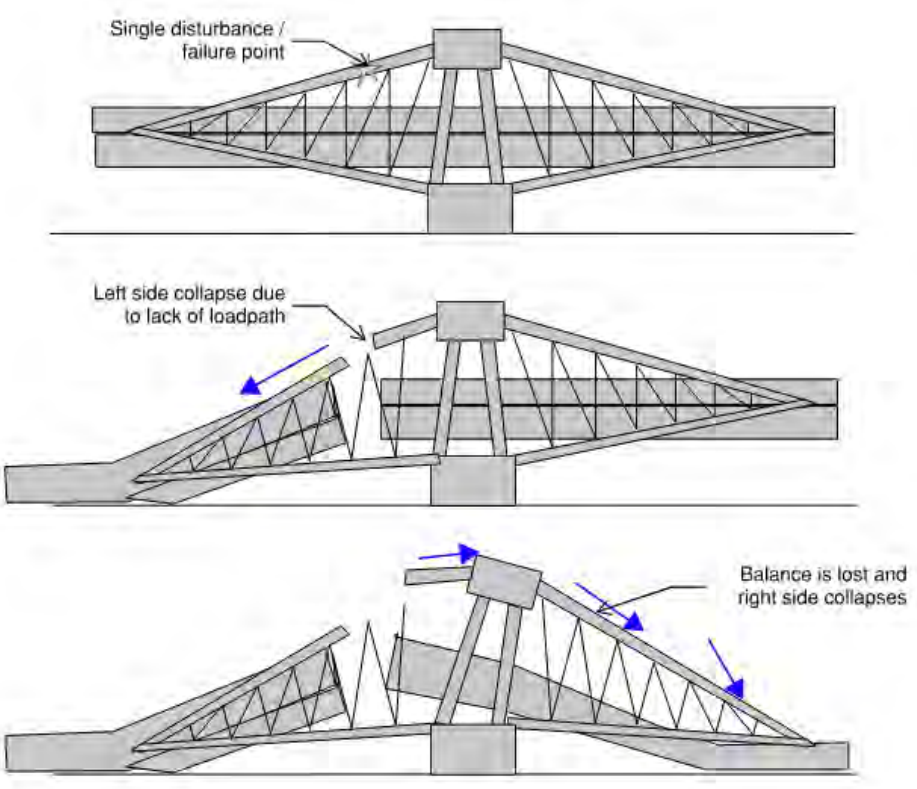

Figure 3 Failure of Truss due to single point failure.

Similar effects are observed when the balanced loading on the span is disturbed.

4.4 Progressive ‘Catastrophic’ Collapse Scenario

The aqueduct is a single connected structure, with the pipe and walkway acting to link all spans together, thus there is the ability for transfer of effects between adjacent spans. This connectivity means that the span collapse mechanism described above could potentially continue and propagate through multiple spans, causing a ‘domino effect’ progressive collapse scenario.

This catastrophic scenario of ‘progressive collapse’ of the bridge is a possibility following a single span failure and reflects a worst-case scenario for the bridge. This is shown in Figure 4 as a continuation of the single span failure described previous:

4. The single span deformation pulls the attached walkway girder beam downward with it and places load on the adjacent truss span (Figure 4 top image)
5. The walkway girder beam movement and load overloads the adjacent span, causing failure of the span. This in turn results in loss of balance at the pier. (Figure 4 middle image)
6. The collapse repeats and propagate over multiple spans, i.e. a ‘domino effect’ (Figure 4 bottom image)

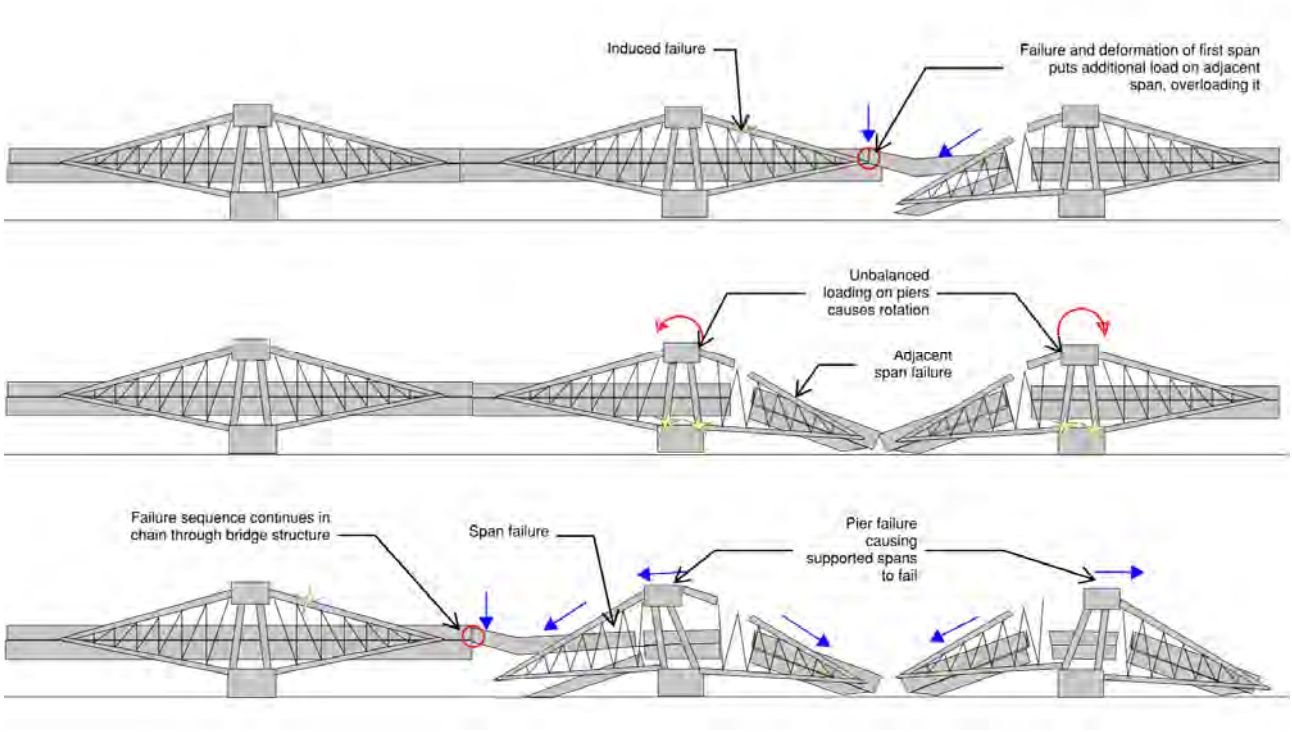

Figure 4 Catastrophic Collapse Sequence

Propping under the trusses aims to arrest the catastrophic collapse scenario by preventing imbalance from a single span failure from causing deformation and loading on the adjacent span.

There are safety challenges with installing and maintaining the propping due to these scenarios occurring during the construction works. These are discussed further in the report.

4.5 Failure Modes and Risk

Due to the limitations of traditional numerical methods as per Section 4.1, failure mode assessment work was undertaken on the existing structure, particularly for safety of personnel during the critical construction phase. This assessment followed the process as below:

1. Identify individual potential failure modes of the structure (i.e. 'top chord failure', 'pier leg failure')
2. Group the failure modes into 'sets' with similar overall outcomes/hazards
3. Assess the relative risk associated with each set.

The Heritage Infrastructure Management Plan (HIMP) Part 1 (August 2022) document provides an overview of the existing structure and introduces mechanisms involved with various failure modes of the aqueduct.

Individual failure modes were identified as part of the HIMP Part 1, and are listed below. These failure modes are described further in the HIMP document:

1. Compressive Failure within Truss
    a. Bottom chord
    b. Vertical web
2. Tensile Failure within Truss
    a. Top chord
    b. Diagonal web
3. Other Failures
    a. Pier Leg Failure
    b. Pier Roof Failure
    c. Walkway Failure
    d. Ovoid Pipe Hanger Failure
    e. Ovoid Pipe Failure
    f. Foundation Failure

From a safety risk perspective, the individual failure modes can be grouped broadly into three sets as below, with a similar hazard from each set. Each is discussed further in the following sections.

1. Sideways collapse –structural failure (or failures) leading to concrete debris falling outside the aqueduct footprint.
2. Vertical collapse –structural failure (or failures) leading to concrete debris falling within the aqueduct footprint
3. Spalling failures - localised chunks of concrete detaching from the structure

The formal risk assessment described in Section 7 expands on these further in the context of the finalised propping design. Refer to Section 6 for the structural engineering solutions developed in response to these hazards.

4.5.1 Sideways Collapse Hazard

Sideways collapse represents the most significant challenge to safely implementing works around the aqueduct, due to the large footprint impacted by the potential collapse mode (refer below for graphical depiction).

The sideways collapse mode is fully described in the HIMP Part 1, Section 5.4. It requires multiple failure points for this mode to be mobilised. We note this failure mode has an **extremely low likelihood** of occurrence during the aqueduct construction works, but due to the unknowns inherent in the existing structure, and the bespoke/untested mitigations to protect worker during the works, there remains a high risk to workers. Refer Section 7 for further discussion on the construction safety risk.

The following is also noted:

- This is a complex failure mode, involving multiple individual members. Refer Figure 5 for the failure mode steps that must occur for this failure to be mobilised.
- The pier legs are in generally better external condition than other elements in the structure. They are not highly utilised in the current condition and show less signs of structural distress.
- Due to the complexity and compressive nature of the failure mode, it is expected that external visual cues, spalling and movement would be present prior to such a failure occurring.

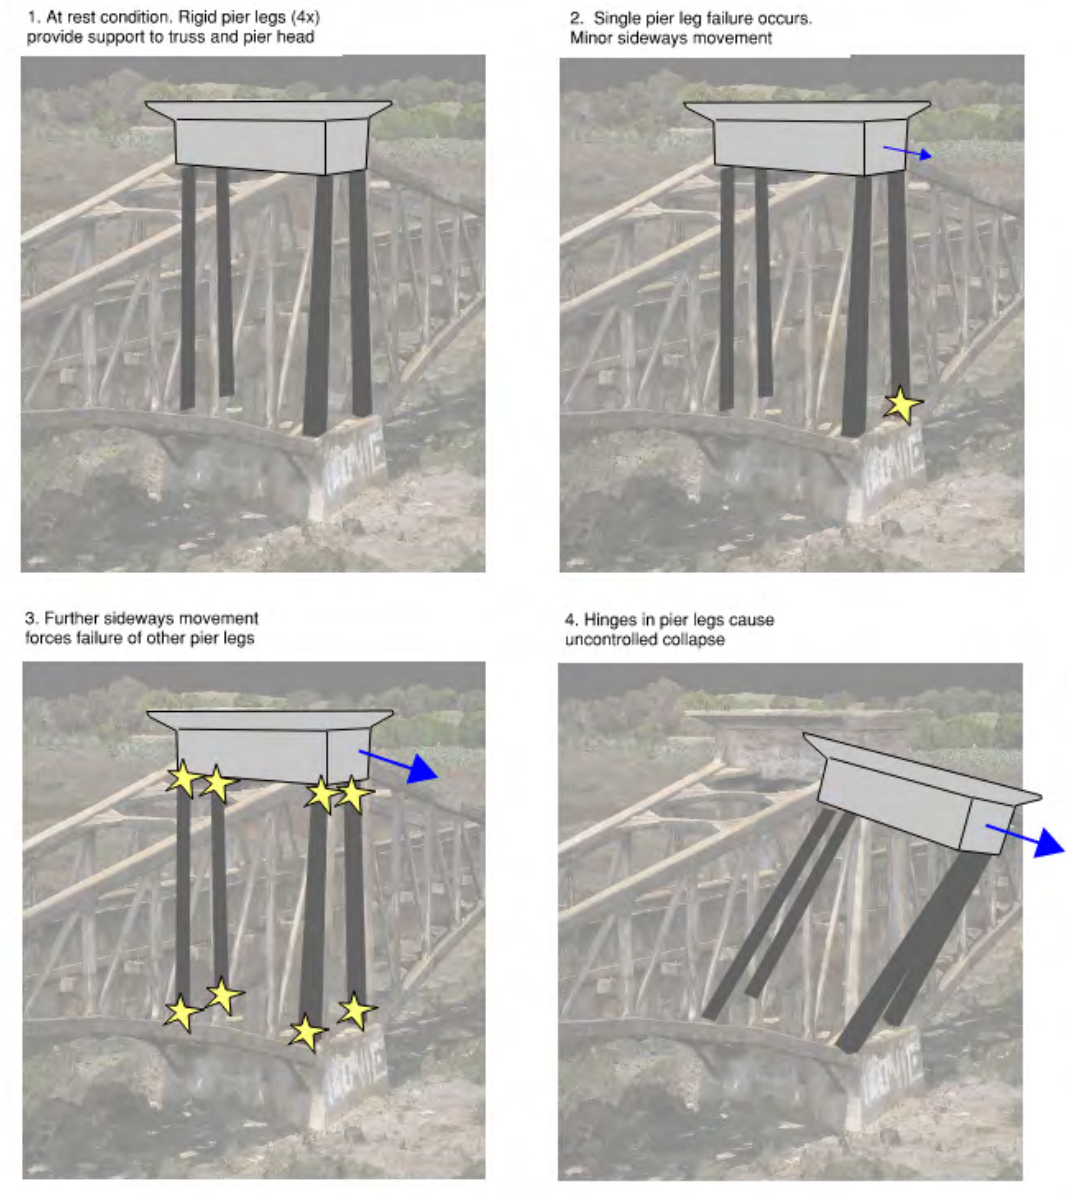

Figure 5 Pier Sideways Failure Mode (unmitigated condition)

The plan zones around the aqueduct structure that are affected by this failure type are shown in Figure 6 below. The dark blue area represents the footprint that can potentially affected by a sideways failure of the tower (max 11.5m from the aqueduct centerline), and the light blue area represents the footprint potentially affected by a sideways failure of the truss (7m from the aqueduct centreline).
The hazard within these footrprints is falling debris from a structural collapse, i.e. large portions of the aqueduct structure falling sideways. The large footprint and massive nature of the potential debris makes mitigation strategies for such an event challenging – development of these are described in Section 6.

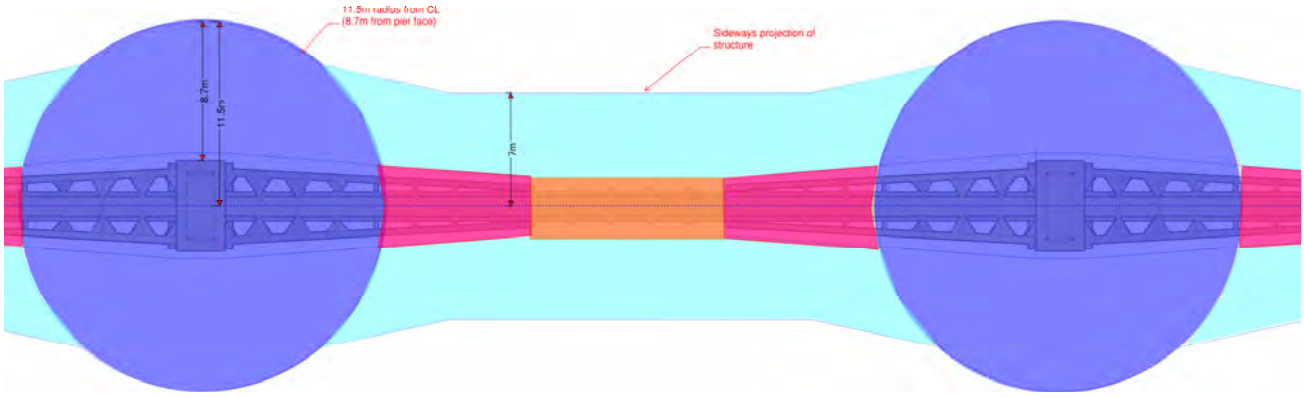

Figure 6 Sideways Collapse - Risk Footprint

4.5.2 Vertical Collapse Hazard

A vertical collapse of the structure (i.e. confined to the footprint of the structure) is far more likely during the construction works, when compared with the sideways collapse mode. The vertical collapse sequence has been shown graphically already in Section 4.3, and can be brought on by many possible single failure modes (discussed at length in the HIMP Section 5). The end result is sections of large concrete debris from a structural collapse falling vertically, under the aqueduct footprint.

Whilst most of these failure modes would have signs of warning prior to failure occurring, there is the possibility of a sudden vertical failure brought on by tensile failure (eg truss top chord), which may not show prior warning signs prior to failure.

Figure 7 shows the risk footprint for a vertical collapse. The coloured areas represent the zone in which large scale concrete debris can be expected under the aqueduct footprint under this type of collapse.

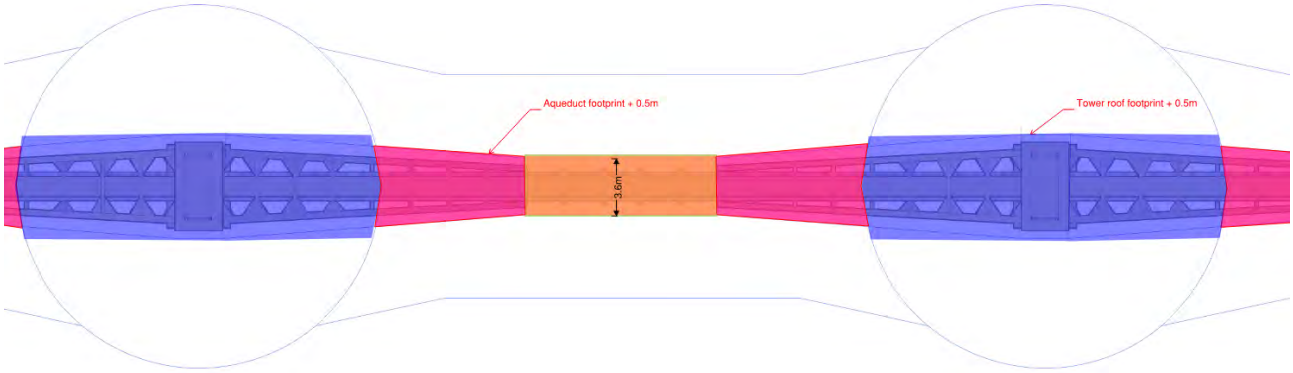

Figure 7 Vertical Collapse – Hazard Footprint

4.5.3 Spalling Hazard

Spalling failure involves localised pieces of concrete debris detaching from the structure and has a high likelihood of occurrence at any time. Spalling typically involves the delamination of cover concrete from structural members constitutes debris with estimated approximate weight up to 100kg.

Evidence of widespread spalling from the structure is already present, with chunks of concrete visible on the ground beneath the structure. Spalling hazards are a risk within the vertical risk zone as shown in Figure 7.

Spalling hazards are more readily mitigated during construction than the wholesale collapse hazards, due to the smaller size of concrete debris associated with a spalling failure. Typically spalling may be mitigated by providing overhead protection to any area with workers inside the defined risk zone.

5. Assessment of Existing Conditions

5.1 Condition Overview

The aqueduct structure has been in a poor condition for several decades, with advanced decay of the concrete being visually apparent in many locations throughout the structure. Propping was installed under Span 14 in the early 1990's due to concerns over the stability of that span, and the structure was fully fenced off in 1995.

The precise level of degradation of the structure is difficult to accurately quantify however, due to the unknown condition of the internal steel reinforcement and its anchorage in the concrete matrix. Nevertheless, external visual inspections provide an understanding of the spalling, degradation of externally visible reinforcement, and degradation over time. A systematic member by member assessment was undertaken by Arup in August 2024, which used three datasets obtained between 2021-2024 to provide a detailed picture of the existing conditions. The full condition assessment has been appended to this report.

5.2 Deterioration – Mechanisms

Deterioration of the concrete structure is due primarily to carbonation of the concrete where the alkaline matrix of the concrete is lost, thus making the internal reinforcement susceptible to rusting, or reducing the effectiveness of its anchorage. The typical sequence of events in the deterioration of a particular element is illustrated in the series of steps in Figure 8 (Condition Rankings as per Arup condition assessment report, ref Appendix B).

Cross Section	Visual	Condition Ranking
 Original cross section	No visible sign of decay	1
 Carbonation	No visible sign of decay	1
 Rusting of bar		2
 Spalling		3 , 4
 Loss of Cover		3 , 4
 Loss of hoop reinforcing		5
 Main bar Loss		5+
Member structural failure follows after critical amount of main bar loss, critical loss of concrete core, buckling of main bars or loss of bar anchorage		5+

Figure 8 Degradation Process and Condition Ranking

Previous engineering reports have discussed at length the deterioration processes on the aqueduct structure, along with measurements of the cover and carbonation depths in various locations. Findings have shown that carbonation depth in the truss members typically exceeds the depth to reinforcement, and that carbonation is the primary mechanism contributing to the structure's deterioration (Taywood Maunsell, 1990).

5.3 2024 Condition Assessment Summary

The Arup 2024 condition report (appended) represents a comparative study of the structural condition at three points in time, based upon separate visual datasets:

- July 2024 – Ground based site inspection (Arup)
- December 2023 - Drone LIDAR (Diospatial)
- 2021/2022 - Archival Photography (Glasshouse)

The primary purpose of the condition report was to prepare a baseline picture of the general structural condition of the structure and identify changes in condition over time, i.e. between the datasets. A condition rating system between 1 and 5 was developed, and a rating assigned for each visible member of the structure, (i.e. truss chord segment, truss web, pipe segment etc), with ratings of '5' representing the worst degraded members, and '1' representing no visual degradation.

There are a total of 2674 members within the structure, and of those, 2083 were able to be visually assessed in all three datasets (noting not all members were covered due to access limitations). The excerpt table below provides a comparative summary of the assessed members across the three datasets, showing the number and percentage of members assigned with each rating value.

Table 1 Member Condition Ratings Comparison for 3x Datasets

Rating	Glasshouse 03/2022		Pointerra Point Cloud 12/2023		Matterport 07/2024	
5	170	8.16%	183	8.79%	184	8.83%
4	347	16.7%	362	17.4%	366	17.6%
3	328	15.7%	346	16.6%	346	16.6%
2	406	19.5%	389	18.7%	401	19.3%
1	832	39.9%	803	38.6%	786	37.7%
Total	**2083**	**100%**	**2083**	**100%**	**2083**	**100%**

Key findings from this data are as below:

1. The structure is degrading over time. During the two years between the datasets, a total of 101 members had degraded sufficiently to receive an increased rating.

2. The structure is in poor condition overall, with only 37% of the members not showing any signs of degradation, and almost 9% of the members showing a critical '5' rating.

Additional datasets are presented in the condition report and show the condition across the aqueduct length, with some spans experiencing more heavy degradation than others. Truss members are in the worst condition, and pier members are in relatively better condition. There are areas where bar ends are visible, indicating that anchorage to the bar has been lost.

We note that no confirmed failures or significant member deformations have yet been recorded in the structure. Whilst heavily degraded members are likely to have lost some of their structural capacity, the imposed load is either still being taken up by the member, or being redistributed to adjacent members, thus avoiding visible signs of failure.

Whilst collapse of the structure is a certainty at a point in the future, it is not possible to accurately predict the current safety factor against failure, the time remaining until the structure will fail, or the exact nature of the eventual failure(s). However, the condition reports provide sufficient evidence to suggest that significant safety risks are present from collapse and that failure cannot be ruled out during the construction period.

6. Structural Engineering for Stabilised Retention

6.1 Lovell Chen/Arup Heritage Impact Statement (2019 / 2020)

As part of pre-permit work, a series of high-level options assessments were undertaken by Arup and Lovell Chen, documented in the Heritage Impact Statement (HIS)[1]. Previously authored engineering investigation reports reviewed during this time (MacLeod, 2016, GHD, 2017) had also investigated options for the structure, and leaned toward a 'managed ruin' approach, rather than considering widespread repair as a realistic option. This conclusion was also reached following the HIS work.

Various intervention types were explored to scope out the project and balance the project outcomes with feasibility. These are summarised below, noting that the assessments were undertaken at a high level, and were based upon a visual inspection of the structure only. Detailed condition and risk analyses were only undertaken during later stages of the project.

6.1.1 Land spans propping

This was identified as the most important and promising of the options proposed because in its most basic form, it enables separation of the connected spans, and with comprehensive propping it can serve as the most effective practical means to mitigate the catastrophic progressive collapse scenario. The 1991 Span 14 propping structure served as a precedent for propping concepts.

Two basic prop layouts were presented, with 'minimal prop' (Figure 9) and 'full nodal propping (Figure 10) being considered. The minimal prop option was purely intended to counteract unbalanced load from separation, whereas the steel truss style prop enabled further protection against catastrophic collapse.

The nodal truss propping was subsequently taken through design development (with a change to a truss style steelwork design, due to effectiveness and aesthetics and a lower piling requirement). Tower propping was not identified at the early concept phase, due to the sideways collapse risk being identified in detail at a later stage in the project.

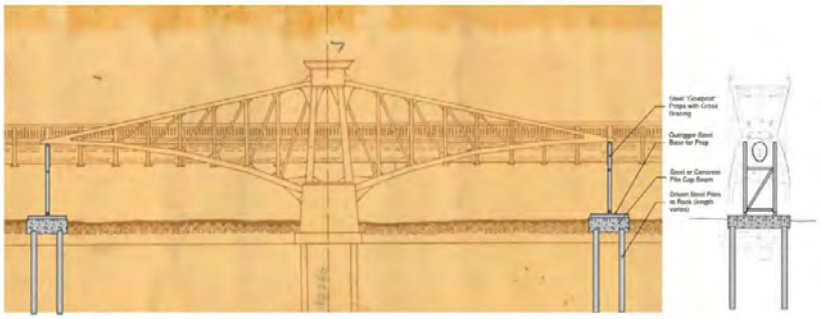

Figure 9 Minimal Prop Option - 2019

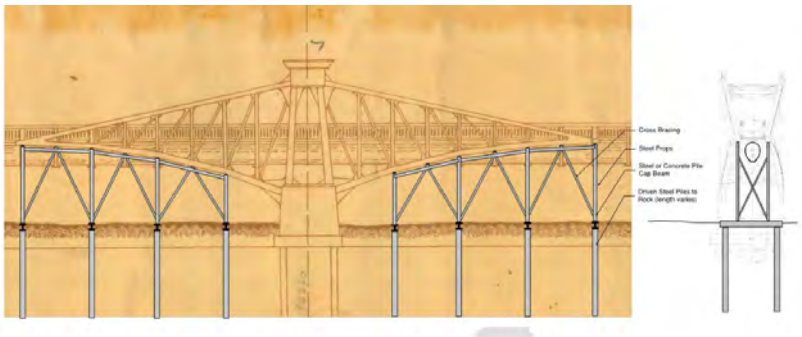

Figure 10 Full nodal propping – 2019

[1] Lodged with Heritage Victoria as part of initial permit application. Updated version lodged April 2020.

6.1.2 River span propping

The two river spans posed a special challenge for propping due to the permanent river channel. A self-supporting structure using pair of steel trusses under the existing concrete bridge was considered during options assessment, however this came with significant constructability issues in terms of ground works, barge operations and craneage in the river channels. Additionally, installation of such a span would require workers in the vicinity of the aqueduct, possibly whilst on barges in the river. This adds significant safety risk to this work, when considered against the land span propping.

Adding a structure below the aqueduct in the river channel also comes with risks in the permanent condition, with significant water loading and floodborne debris having the potential to cause failure of the propping and the aqueduct structure above.

After considering a combination of the scale of works required, feasibility, performance and safety, river span propping was assessed as being unfeasible and was not taken forward with the scope of works in the heritage permit.

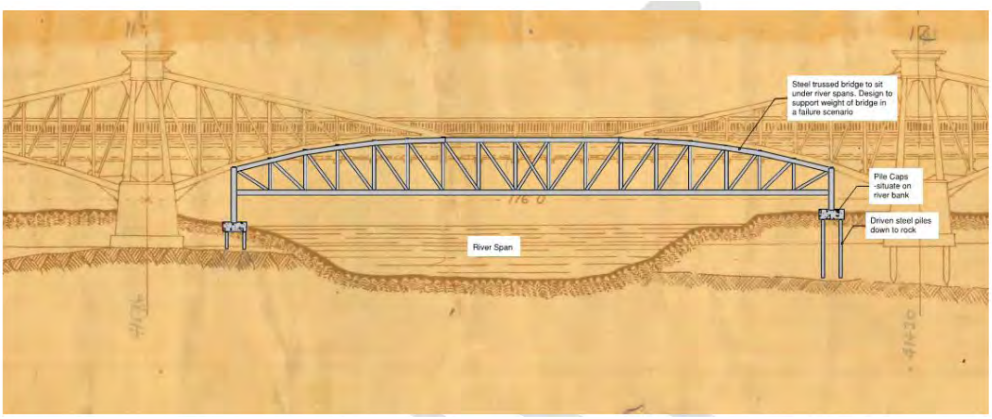

Figure 11 River Span Propping Concept - 2019

6.1.3 Restoration

Restoration of the structure was acknowledged as the only suite of options available that improves upon the current structural condition. Local restoration works are also prerequisites for the effective application of any corrosion inhibition measures (refer below).

In practice, restoration of the degraded structure would involve a combination of patch repairs and more invasive recasting of entire members of the structure, given their small cross-sectional size. The heavy state of degradation would likely require much of the existing reinforcement to be replaced, which would ultimately result in entire members being rebuilt. This process would require significant temporary works and stabilisation and would increase the risk of structural failure during the works. Any restoration works would involve workers being up close to the structure, and spending significant time working underneath the aqueduct structure.

The present condition of the Aqueduct structure unfortunately makes many of the reviewed techniques unlikely to be effective from a performance perspective. Liaison with concrete repair specialists during the study did not offer any viable options for the restoration of concrete structure in such an advanced state of deterioration with the construction services firm SRG Global providing detailed input on the various possibilities.

Feasibility of the restoration option was assessed as being dangerous, technically challenging and likely ineffective, therefore it was discounted as part of the assessment works.

6.1.4 Reduction of load on aqueduct

Reducing the load on the bridge was considered in an attempt prolong the life of the structure. The aim of load reduction is to reduce the structural stress on the members, thus allowing the members to accommodate a higher amount of corrosion before they fail.

In practice, this would be an invasive action involving removal of secondary structure that are still integral parts of the aqueduct (pipe, walkway etc), refer Figure 12.

Removal of the ovoid pipe or walkway would be a challenging technical process as works would need to be carried out directly under the structure, and even within the trusses. Load removal would need to be carried out in a balanced fashion across the entire Aqueduct, along with significant temporary propping to avoid unbalancing the cantilever trusses. Worker safety was recognised as a major issue with this option.

Removal of the ovoid pipe will not eliminate the risk of progressive collapse and would change the Aqueduct's visual character and the legibility of its original designed function. The option was discounted due to technical feasibility of the removal, and the loss of place that would result from the drastic intervention.

Removal of the walkway would cause a loss of the aqueduct's continuity and result in a series of disconnected piers. Propping associated with this option would be extensive and subject to the same safety risks as described further in the report, with additional risks of working directly inside the trusses. Furthermore, the walkway currently offers additional structural stiffness to the trusses, with unknown consequences for the remaining structure if it was removed. Thus the walkway removal option was discounted on these grounds.

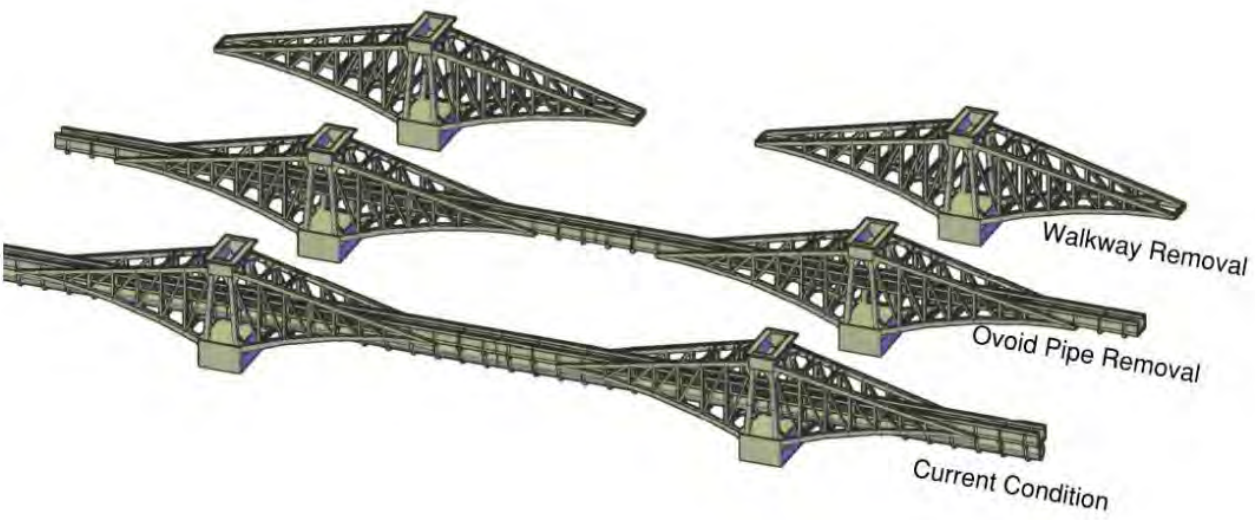

Figure 12 Reduction of Load Considerations

6.1.5 Actions to slow structural decay

A suite of potential actions to arrest or retard the rate of structural decay had been considered historically. Successfully slowing the rate of decay would have the potential to prolong the life of the structure. These methods do not on their own address the current condition of the structure – they would be required to be used in conjunction with other means if any improvement in the condition is desired.

These actions were reviewed again during options assessment, however liaison with specialists found that the condition of the structure rendered the reviewed techniques unlikely to be effective from a performance perspective as discussed below.

Electrochemical methods:

These slow decay by addressing the chemical conditions within the concrete that allow corrosion of the steel inside. These methods employ either passive or actively generated electrical currents, either to change the chemistry of the concrete so that corrosion occurs at a slower rate or to provide an alternative (sacrificial)

element that can corrode in place of the structural reinforcement. The following available methods were reviewed:

- Realkalisation – this aims to increase the pH of already carbonated areas of concrete back to alkaline levels, thus protecting the reinforcement within. Trials had been undertaken in 2009 on the aqueduct structure, but results suggested this was not technically feasible as pH was not raised sufficiently. Additionally, realkalisation requires sound concrete and electrical continuity of reinforcement, two things that are not present in the aqueduct and would require significant work to achieve.
- Cathodic Protection - involves connecting the reinforcement structure to a sacrificial anode, so that the ongoing chemical activity corrodes the anode rather than the reinforcement. The use of impressed current to make this connection requires a current generator to be permanently installed; on remote structures this is typically a battery-based application that requires ongoing monitoring and service. Similar to realkalisation, the effectiveness of cathodic protection requires sound concrete and electrical continuity of reinforcement, two things that are not present in the aqueduct and would require significant work to achieve.

Surface coatings:

Surface coatings are only effective in reducing deterioration in sections of the structure with sound, non-carbonated concrete where the material cover has not failed (or following overhaul repairs that restore such deteriorated sections.) Due to the extensive repairs that would be required as a prerequisite and works underneath the structure, surface coatings were not viewed as a feasible option supporting the retention of the structure without accompanying restorative repairs.

6.1.6 Demolition and Outcomes

Demolition of the aqueduct structure resolves the ongoing risks to public posed by the deteriorating structure and allows the river to be reopened. Outside of the heritage context, demolition is the expected resolution to a non-serviceable and redundant piece of infrastructure.

It was recognised at the time of assessment that demolition (partial or whole) may be the only outcome that allows for the feasible achievement of other identified management objectives, in particular the resolution of public access and stewardship and reconciliation objectives with respect to the river.

Following the options review, a partial demolition option was presented as preferred in the Heritage Impact Statement (2020), involving demolishing the four river spans and propping of the cut ends of the remaining structure, to balance the loads and prevent a collapse brought on by the separation (refer Section 4.2). This option was subsequently scoped in the heritage permit P32806, along with additional conditions for conservation works to the remaining structure.

6.2 Heritage Permit – Structural Design Brief

The heritage permit P32806 was issued in November 2020 for demolition of four spans of the structure, and included conditions for 'conservation works' as follows:

> *20. …. The purpose of Stage 2 Conservation Works Package is to undertake conservation works that will reasonably avoid the catastrophic collapse of the Aqueduct structure, taking into consideration the flood prone nature of the site, the forthcoming demolition works, and to secure the long-term future of the structure….*

This definition was used as the basis for three broad engineering design criteria to inform the propping of the remaining structure:

- Provide a load path for unbalanced forces created by the separation of the structure, and avoid a collapse induced by the partial demolition works.
- Provide additional load path against single span truss collapse in event of a future single member failure in the primary bridge truss structures.
- Reasonably avoid the catastrophic collapse failure, i.e. a progressive collapse 'domino effect' scenario of multiple bridge spans.

6.2.1 Limitations of Propping Intervention

From the outset, propping had a limited use and purpose. It was not intended to prevent local failures of the structure, or improve its structural condition – only to prevent a catastrophic total failure. The HIMP Part 1 document (a condition of the heritage permit P32806) contains further details regarding specific failure modes of the aqueduct including where propping interaction will affect the behaviour following specific failures.

After completion of any propping works, the condition of the remaining aqueduct structure will continue to decline unabated over time, at its current rate of deterioration. This will eventually lead to visible failures within the structure, as local members deflect due to inability to carry load. Figure 13 shows an indicative view of the eventual failure sequence after the installation of propping to the structure, with gradual decay leading to an eventual loss of the aqueduct's shape and rubble forming on the props.

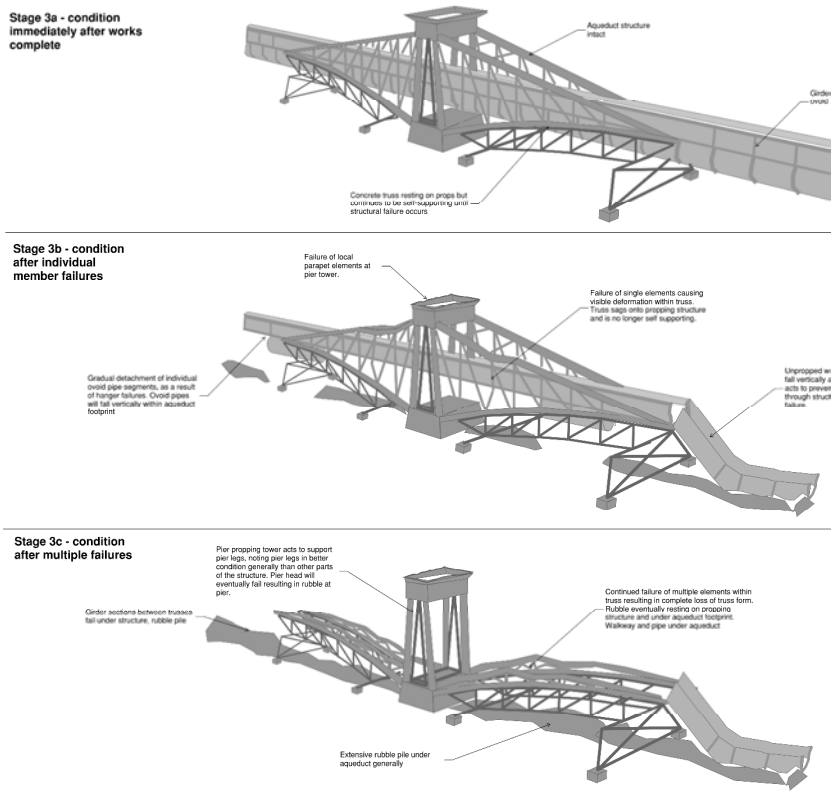

Figure 13 Failure Sequence after Propping Installation

6.2.2 Long Term Propping Behaviour

The static propping structures are robust, however the lack of access for long-term maintenance of propping is a consideration in assessing their viability and effectiveness.

Immediately after installation of the propping, the risk zone around the aqueduct would be fenced off and isolated from the public. The aqueduct will continue to degrade further per Figure 13, and within the cordoned areas, the safety risk for any required works will increase due to local failures, spalling and collapse.

Because of the increased safety risk and instability of the aqueduct following localised failures, there is not an intent to maintain propping structures after their initial installation, other than managing vegetation under the propping. The steel propping can be designed for minimal maintenance and a long service life with appropriate coatings, but eventually it will begin to degrade, requiring repainting, rust removal and possible regrouting. Some limited maintenance from the safe areas at a distance is possible, (i.e. sand blasting and spray paint) but this unlikely to be fully effective due to the long reach required.

The 1991 propping is a case study for real world long-term performance of steelwork propping. It has not had any maintenance since its installation, due to the safety risks associated with this activity. The painted steelwork propping was inspected as part of the exploratory works and is generally in sound condition after 34 years, but over the longer term (a period of decades) the propping structure will continue to degrade until rusting of the steel structure and eventual failure to support the aqueduct rubble.

6.3 Early Propping Design History (2021-2023)

For propping to respond to the brief set out in the heritage permit, it must be installed under all trusses and towers of the aqueduct. This scope of propping simultaneously addresses the unbalanced load path created by demolition, as well as reasonably avoiding the catastrophic collapse failure. It was recognised at the start of design works that, due to the repetitive nature of the aqueduct structure, the propping could be a system with individual 'modules' of similar design that could be installed under the trusses and towers.

Initial design of the propping systems was undertaken by WGA and McMahon Constructions, with Arup acting as a technical reviewer. Early 'active' propping concepts were put forward by WGA /McMahon comprising cable stayed interventions acting to support the trusses. These were in turn supported on the existing pier towers, in an effort to reduce the requirement for piling.

There were significant issues raised regarding the efficacy of such systems, and following workshopping and review, these were abandoned in favour of a fully 'passive' propping philosophy, which comprised steel trusses under the existing aqueduct trusses, and steel frames installed inside the existing aqueduct piers. The passive propping philosophy involves installation of the modules under the structure without preloading or jacking, where the propping system is only 'activated' following a failure of the aqueduct concrete structure.

Reviews during the design phase resulted in numerous changes to the design during early development, however it should be noted that the principal focus during design work was developing the efficacy of propping in its permanent condition, with construction/installation being a secondary focus.

6.4 Revised Design with Focus on Construction Safety (2023-2024)

The Heritage Infrastructure Management Plan (HIMP) Part 1 document was prepared concurrently with the early propping design work. The HIMP was prepared with future state considerations, and did not have a construction phase focus. Knowledge gained during preparation of the HIMP allowed for detailed understanding of the structure's failure modes and risks posed by the structure, which also could be applied to the construction phase works.

The HIMP Part 1 led to the creation of the risk zone footprints (refer Figure 6 and Figure 7), which drove thinking around safety during construction of the propping. A series of workshops were held in 2023 with all project parties (Barwon Water, WGA, Contractor, Arup) regarding construction safety of the propping. Following the workshops, some unmitigated construction safety issues remained with the WGA design, as summarised in Figure 14 below.

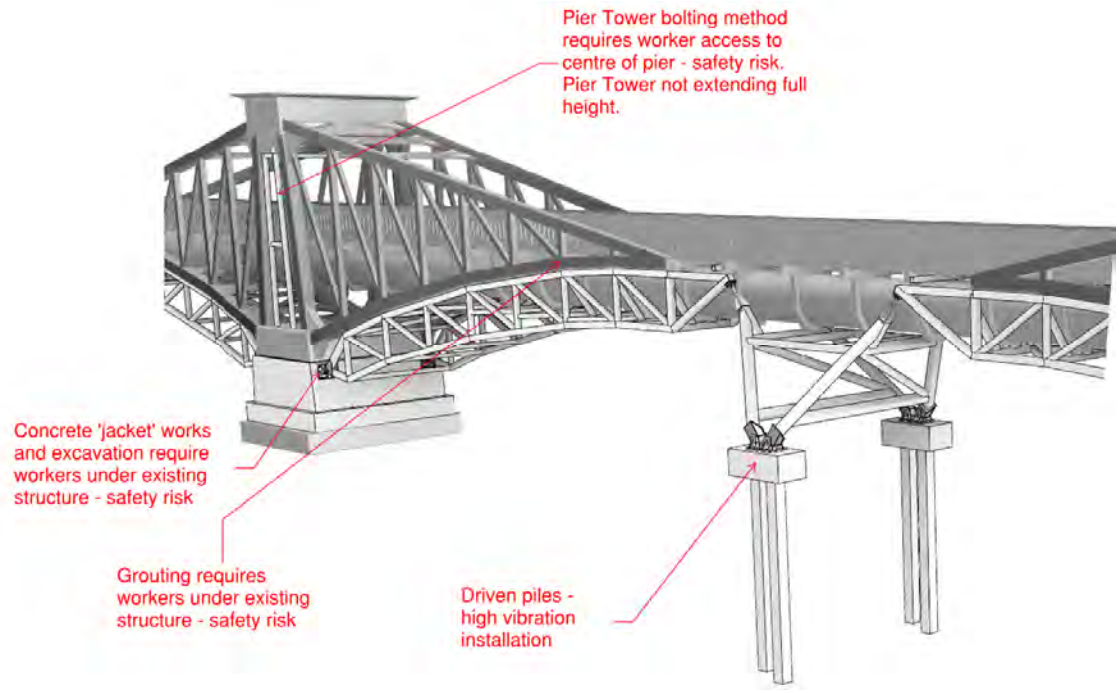

Figure 14 WGA Propping Design showing Possible Installation Risk Items

Arup took forward the design role for the propping from WGA in August 2023, with a revised concept being put forward by Arup at this time. The design was coupled with a range of mitigations proposed to reduce the identified risk where risk could not be designed out. A summary of the Arup design and mitigations is below, highlighting design risk eliminations that were implemented.

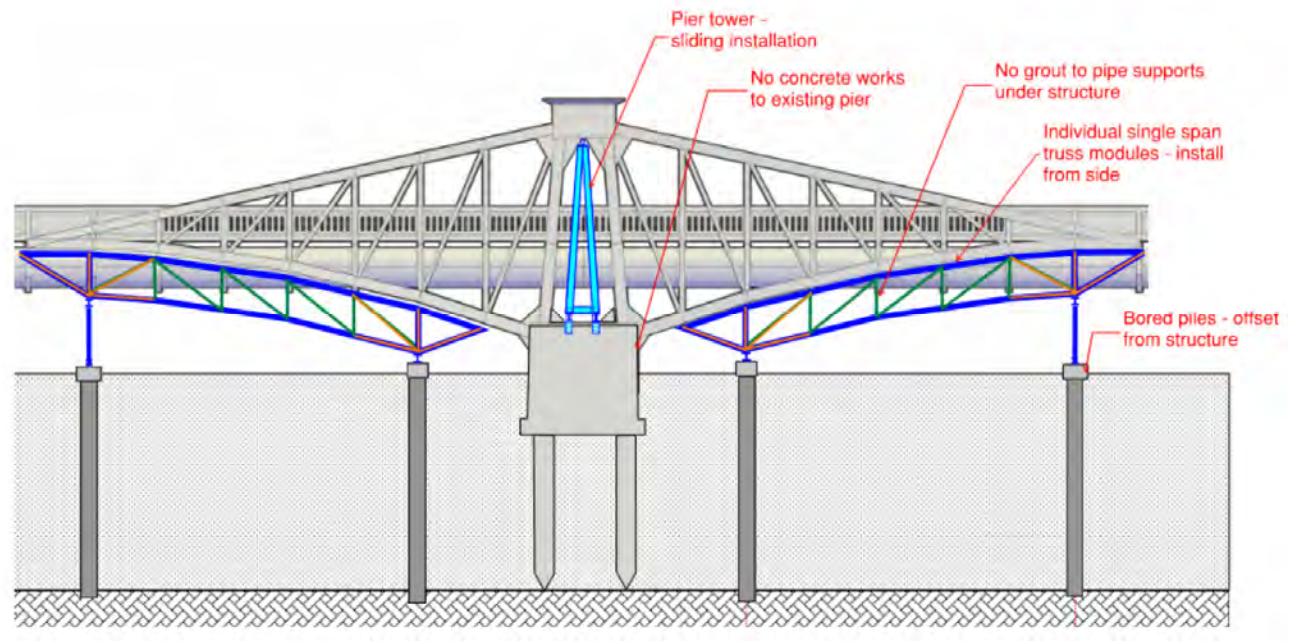

Figure 15 Arup 2023 Propping Design Features

6.4.1 Design Elimination of Risks

The highest risk during construction is directly under the structure, arising from a vertical collapse or spalling. The previous WGA scheme included significant works under the structure. Mitigation (elimination) of this particular risk was undertaken through redesign, whereby installation details of the propping structure were altered so the system could be installed without requiring any worker access underneath the structure.

Design changes associated with this design change risk elimination involved:

- Removal of concrete jacketing to existing piers
- Prefabrication of all steelwork elements and sliding installation methodology
- Offsetting of piles away from the highest risk areas
- Changing high impact driven piles to low impact bored piles
- Incorporation of a ‘grout bag’ detail for final grouting of the steel-concrete interface.
- Removal of grouting to pipe supports (only grouting for truss chords)

6.4.2 Mitigations of Remaining Risks

Following elimination of as many risk items as possible by design, the most significant remaining design challenge for construction safety was the sideways collapse mode, due to the large exclusion zone for this scenario, and large mass of potential debris (refer Figure 6).

Whilst alternatives were extensively tested, there was no feasible design solution identified which could keep workers completely outside of the sideways collapse risk zone (refer Figure 6) at all times during the installation. Certain activities associated with propping installation require workers to be within 1-2m of the structure at specific times during the installation process, in particular for piling works, during the final grouting process and for bolting steelwork modules together.

Therefore the team explored and workshopped mitigations to reduce the risk during the short periods of time that workers would be required to enter the sideways collapse risk zone, including temporary shielding, which involved erecting a heavy-duty overhead protection above any works zones. Ultimately shielding was discarded as a valid option due to the massive nature of required equipment to withstand a wholesale structural collapse.

Due to the unique nature of the remaining risks posed by the existing structure and the inability to undertake works fully outside of the exclusion zone, the 2023 design included a suite of mitigations proposed to improve worker safety as below.

1. Physical Mitigations:

a. Temporary stabilisation of the pier head against lateral movements – incorporation of cable stayed basket (see below)
b. Provide temporary overhead hoarding for spall protection (10kPa Class B protection) -required anywhere within 1m of overhead concrete.
c. Stop works in high wind conditions

2. Management / "Administrative" Mitigations

a. Install real-time position monitor to detect movement of the pier head, with alarm for movements detection
b. Install vibration monitoring with real time alarm
c. Daily visual inspection of pier legs and pier (Contractor) checking for spalls, cracks, deformation
d. Posting a spotter whenever people are within the outer exclusion zone boundary.
e. Brief all personnel working in the area on the risks and have action/evacuation plan in the event of alarms/spotter alert

6.4.3 Temporary Pier Head Stabilisation

Of these mitigations, the temporary stabilization of the pier head against lateral movements was the most important physical intervention, to reduce risk from the sideways collapse mode by 'catching' the structure before it fell.

This is an engineering control, which aims to maintain the pier in a vertical orientation in the event of an incipient pier failure and prevents a single point failure from deflecting significantly and 'dragging' the remainder of the tower sideways. The incipient pier failure could originate at any of the 14 pier heads, and because they are all connected, the temporary stabilisation would be required at all pier heads before work around the structure could commence.

The stabilisation structure involves a lightweight structural steel 'basket' to be mounted in the existing pier head, with 4x inclined cables anchored to concrete blocks. Refer Figure 16 below for an overview of the temporary stabilisation structure.

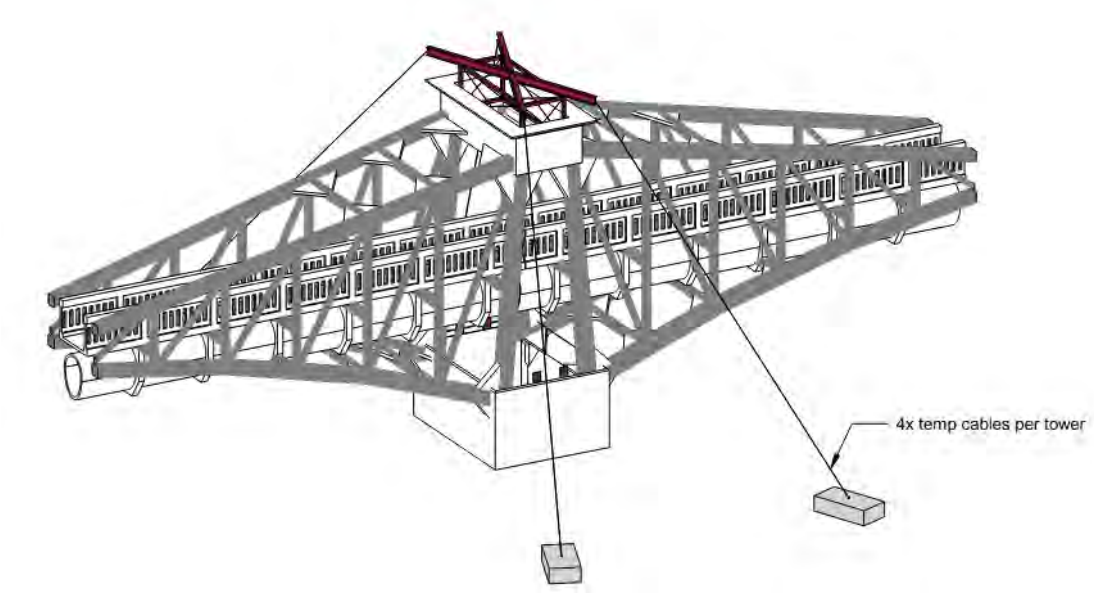

Figure 16 3d image of Temporary Pier Head Stabilisation

Design of the stabilisation structure and cables is intended to provide an external load path in the event of an incipient sideways movement of the pier. If the incipient failure causes the pier to move a small distance sideways due to a local failure (per step 2, Figure 5), then the stabilisation structure would be activated and limit further sideways movement by providing an independent lateral loadpath (refer Figure 17). Additionally, a position monitor would provide warning of the movement, thus allowing evacuation of the site. The stabilisation structure was designed to be installed from a crane above, without requiring worker access to the high-risk zone around the pier.

Whilst the stabilisation structure acts to control the sideways failure mode and reduce the risk associated with this collapse mode, it also adds some safety risks for construction such as potential impacts to the stay cables during works and for the install procedure of the 'basket' on top of the pier head, particularly with the soft ground conditions in many parts of the site.

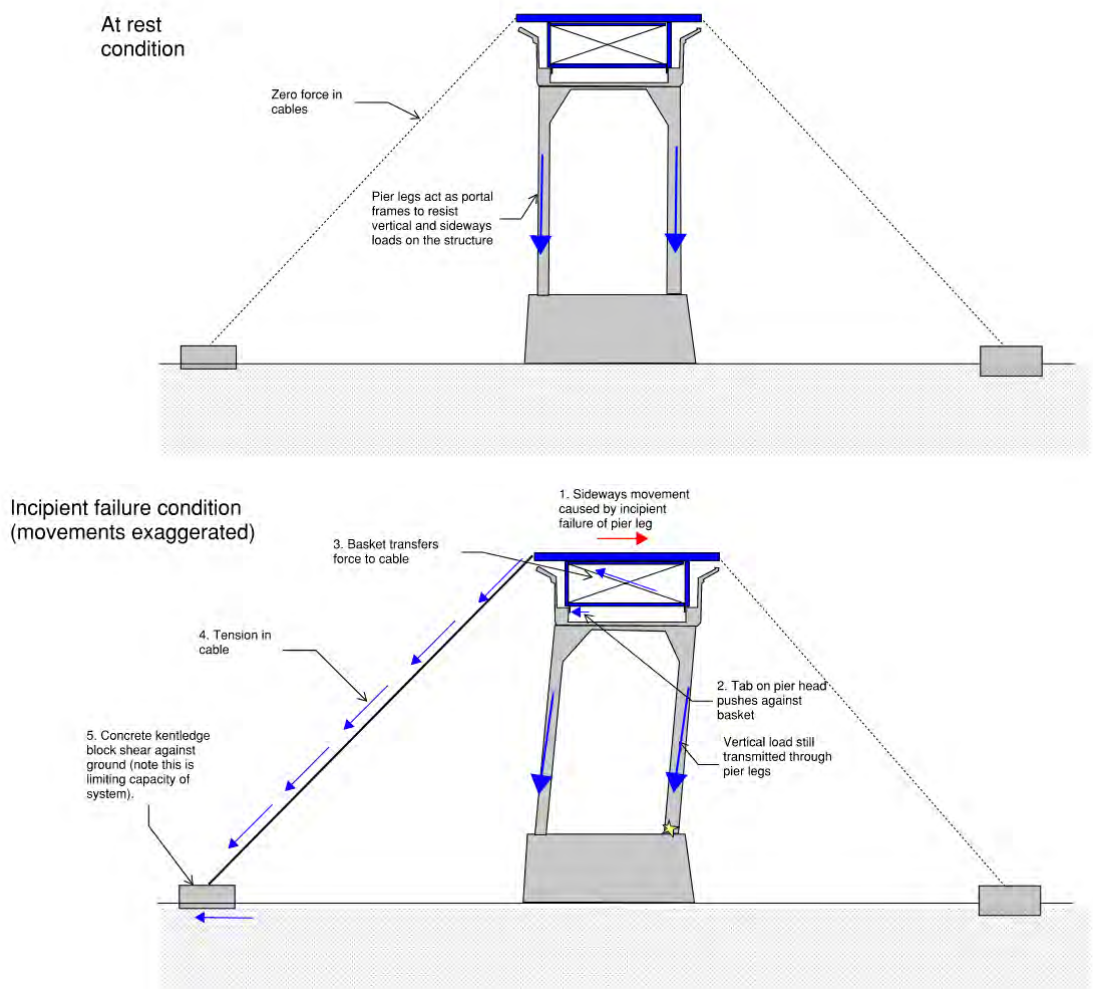

Figure 17 Load Path Diagram for Temporary Pier Head Stabilisation

7. Risk Assessment of Finalised Propping Scenario

Once the final design and mitigations were workshopped, they were then taken through a formal risk assessment process to assess the residual risks against Barwon Water's Risk Management Framework. This process and results are described below.

A risk assessment for the construction of the finalised propping scope was conducted in accordance with Barwon Water's Enterprise Risk Management Framework (ERMF) (Version 3.0, February 2024) and the Occupational Health and Safety Act 2004 (OHS Act). The ERMF, which aligns with ISO 31000 and the Victorian Government Risk Management Framework, defines Barwon Water's low tolerance for harm to people, contractors, and the public, and a similarly low tolerance for environmental impacts that could affect its licence to operate or areas of cultural significance.

Under these obligations, Arup, in collaboration with Barwon Water, Lovell Chen, and Simpson Construction, led a formal risk assessment aligned with both WorkSafe Victoria guidelines and Section 20(2) of the OHS Act. The process assessed:

- The likelihood and consequence of risks eventuating,
- What was known or should reasonably be known about each risk,
- Options to eliminate or reduce each risk,
- The feasibility and cost of available controls.

A Delphi Method workshop (as per ISO 31010) was used to gather expert consensus. Three principal structural failure modes were identified as already discussed above:

- Concrete spalling (localized delamination and deterioration) – refer Section 4.5.3
- Vertical collapse (catastrophic failure of piers or spans) – refer Section 4.5.2
- Horizontal collapse (outward or lateral truss failure) – refer Section 4.5.1

These failure modes were assessed to have inherent risk ratings ranging from high to extreme, primarily due to the degraded condition of the structure and the potential for serious injury or fatality. In response, Arup undertook design changes for elimination where possible, and then developed a range of potential controls for the remaining risks, which have been described in Section 6.4.2. These were evaluated in a formal risk workshop held on 29 August 2024. The outcomes of the control evaluation are summarised in Table 1, with the full residual risk tables for the three failure modes appended as Appendix A.

Table 2 Hazard Control Quantities Post Workshop

Hazard	Approved Controls	Partially Approved	Rejected Controls
Concrete Spalling	9	5	2
Vertical Collapse	18	2	9
Horizontal Collapse	24	1	7

The residual risk levels were recalculated following implementation of the proposed controls:

- Risks associated with spalling were reduced to insignificant to medium,
- Risks associated with vertical collapse remained between medium and high, largely due to the severe potential outcomes, despite low likelihood,
- Risks from horizontal collapse were reduced to medium.

Importantly, the “high” residual risk related to vertical collapse applies to the “Business as Usual” (BAU) scenario—i.e. the risk posed by deterioration if no works are undertaken—underscoring the importance of timely remediation. While many controls help reduce risks, the inherent condition of the structure means certain interventions (e.g. installing supports) expose workers to the very risks they aim to mitigate.

In summary, while the risk assessment identified a number of controls in-line with the requirement to minimise risks So Far As Is Reasonably Practicable (SFAIRP) as part of the remediation scheme, the residual risks to safety remained medium and high (principally due to the potential for serious injuries and fatalities). The primary control of temporary pier head stabilisation is a bespoke intervention, and the majority of other controls were administrative in nature.

These risks could not be reduced further within the context of the proposed propping schemes and as such, to further minimise or eliminate risks to safety in-line with Victoria’s OH&S Act, consideration of schemes that minimise human interaction with the Aqueduct (including demolition) would be needed.

8. Modular End Propping – Alternative Scenario (2024)

8.1 Background

Following the risk assessment and residual safety challenges with installation of the propping design, an alternative design scenario was contemplated in late 2024. This scenario - the 'modular end propping' - sought to investigate whether a redesigned propping intervention could derisk the installation works sufficient to allow for the partial demolition scope to proceed.

Fundamentally, the modular propping is a less substantial intervention to the structure than the truss propping scheme and aims to provide permanent propping only to the truss tips at the end spans of the retained structure after demolition (piers 8 and 13). The purpose is purely to counteract imbalances generated in the structure at demolition and avoid a demolition-induced collapse during decoupling. It does not address long term stability/ or catastrophic collapse of the structure, due to the more limited interaction between the props and the existing structure (i.e. only at the truss tips), and the fact that there is no tower propping. Figure 18 shows the modular propping and features.

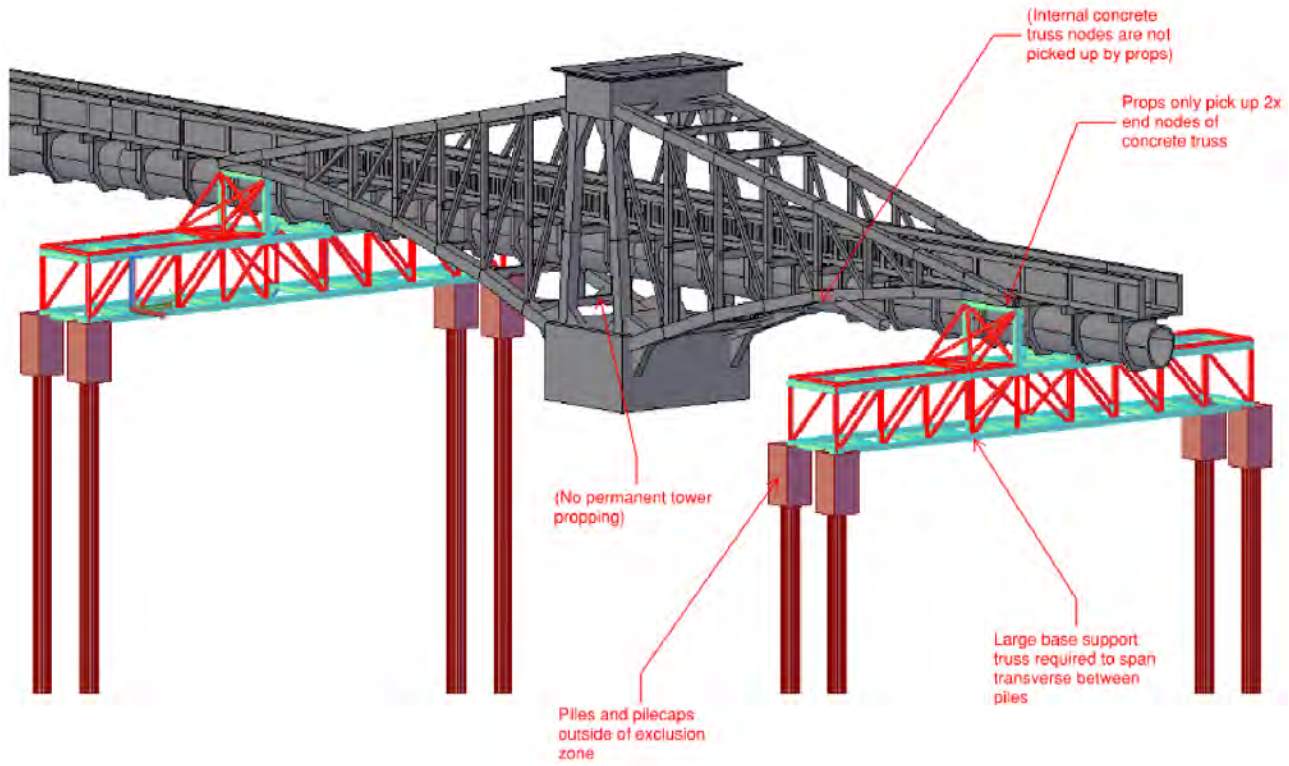

Figure 18 Modular End Propping - Key Features

The main distinctions of the modular end propping that give it an improved construction safety profile when compared to the original propping are:

1. Tower prop modules are completely removed
2. Piling and ground works constructed outside of the sideways collapse exclusion zone
3. There are fewer contact points with the existing structure.

Figure 19 shows the modular propping installation sequence, illustrating the sliding mechanism to avoid works in the exclusion zone.

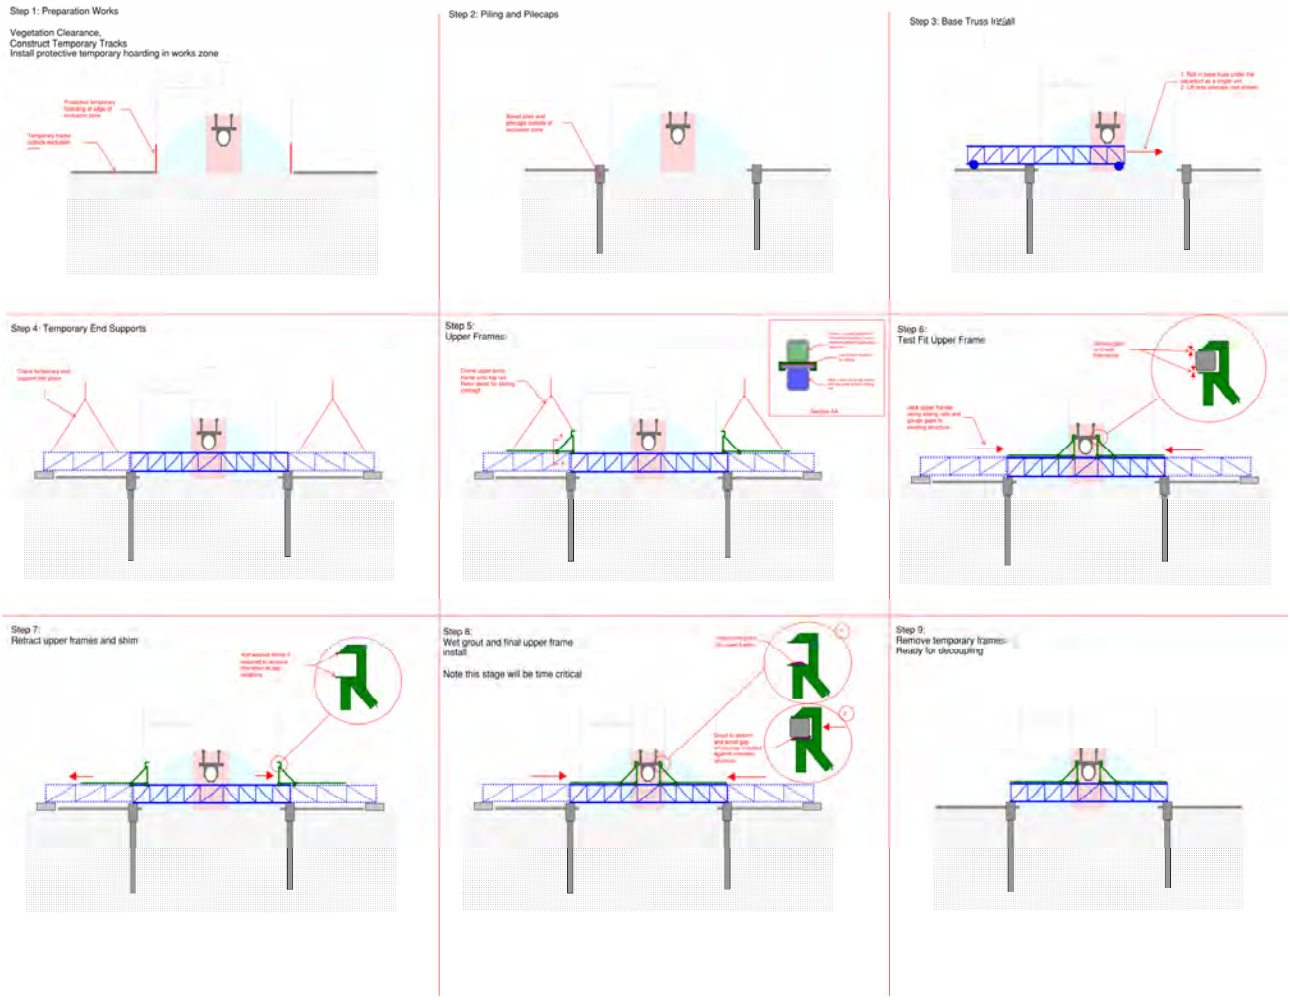

Figure 19 Modular Propping Install Sequence

8.2 Challenges

8.2.1 Construction Phase – Grouting Process

Whilst the modular end propping design mitigated many of the residual construction safety risks, a key challenge that remained was the interface between the prop structure and the existing concrete truss chord.

Detailed numerical modelling was undertaken which showed that any gaps between the prop and concrete would result in poor behaviour of the existing structure. Therefore for the propping to be effective, closing this gap was a key requirement. A remote system of grouting the gaps using grout bags was proposed, with grout pumping investigated.

Physical trials were undertaken on 1:1 scale models of the prop/aqueduct geometry, suggesting technical viability of the system with pumping of grout into the bags. However considering the approach holistically, it must be acknowledged as a bespoke application with the potential for technical failure. There is little redundancy if a technical failure does occur, i.e. if the grout bag system did not work, then any rectification or alternative methods for install would face the requirement for personnel to enter the risk area.

Figure 20 Grout Bag Trial

8.2.2 Residual Risks to Public

Even if the propping could be successfully installed, the remaining aqueduct structure will continue to pose a residual safety risk in the long term. This risk exists only within the proposed fenced area around the remnant structure. Affected parties are Barwon Water employees entering the perimeter for future maintenance works, and any members of the public who access the perimeter in an unauthorised manner. Whilst there is a robust fence proposed, it can deter access into the perimeter but not fully prevent it. The quantification of this risk was outside the scope of the construction risk workshop, but it is important to note that the presence of the decaying aqueduct structure, even if fenced, will continue to pose a safety risk.

9. Demolition Proposal

9.1 Background

As the previous sections have illustrated, all interventions examined to date during the extensive design period involve the presence of workers within a defined risk area around the aqueduct structure. Despite significant efforts by the project team, construction phase risks associated with retention and propping of the structure could not be reduced below the SFAIRP threshold.

Additionally, a 'do nothing' approach represents a significant risk to public safety and does not allow for the Barwon Water and surrounding area to be safely reopened to the public.

Thus the only viable option available to decrease the risk profile to a SFAIRP level is the safe demolition of the aqueduct superstructure, with retention and works to the pier base elements undertaken after elimination of the overhead structural risk and debris removal.

9.2 Scope of Works

The referenced Arup drawings document the scope of the demolition and retention works. The scope of works is provided below as a summary.

1. Demolish the entire aqueduct superstructure above the pier bases.
2. Retain all pier bases, and the stair/landing structures at the northern and southern ends of the aqueduct. Possible opportunistic salvage of other elements upon assessment after demolition and making safe (i.e. sewer pipe at ends of structure)
3. Cut all pier bases down to 1m above ground level (fall risk minimisation)
4. Patch repair all remaining concrete
5. Provide new 150mm concrete slab as a cap for the cut down pier bases (noting the pier bases have a rubble fill construction).

The proposed scope of demolition is shown graphically below.

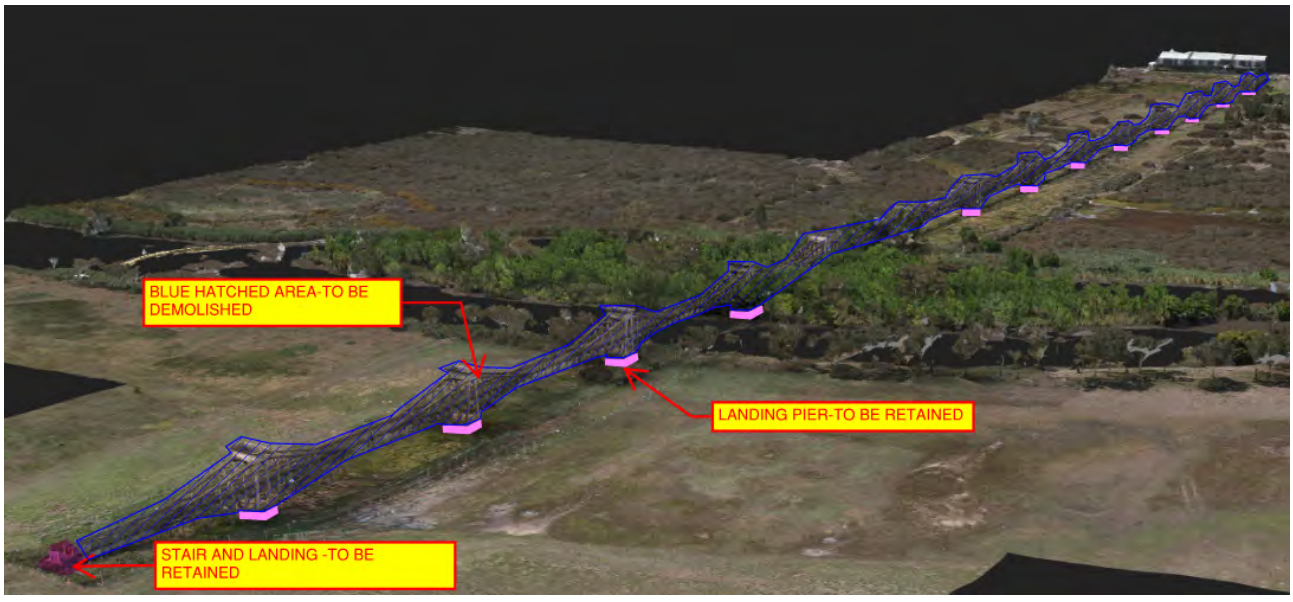

Figure 21 Proposed Scope of Demolition

9.3 Demolition Considerations

Some unique aspects of the existing structure must be considered by the Contractor when developing the demolition methodology:

1. The previously defined exclusion zones should apply for any preparatory works required around the structure ahead of demolition whilst the aqueduct is standing (refer Figure 6 of this document).
2. A controlled 'step by step' dismantling of the structure may or may not be feasible. The following aspects shall be considered:
    a. There is a lack of redundancy in the structure - for example if a single truss member is cut, there is a high likelihood of the entire truss failing (refer Section 4.3).
    b. The interconnected nature of the structure means that a single span failure may lead to a domino effect of multiple spans collapsing (refer Section 4.4).
    c. The structure relies on balanced loading for its stability - if elements are removed in an asymmetric manner that creates imbalance, this could lead to failure.
    d. Temporary propping may be challenging to install, given the exclusion zones and risks presented in this report. This may result in a demolition method that does not rely on propping.
3. The possibility for a lateral/sideways collapse during the demolition works should be allowed for and should help to inform exclusion zones during demolition

9.4 Works to Retained Elements

The only components proposed for retention are the stairs and landing at each end of the structure, and the lower portions of the primary pier bases.

The staircases are structurally independent from the main truss spans and piers, and it is feasible to retain them without significant impact from the demolition works.

The retained pier bases sit underneath the main superstructure, and are robust structural elements. Depending on the demolition method and process, these elements may be impacted by the demolition works. Falling debris may strike the pier bases, causing some local damage to their top parts. However, given that the top of the piers will be eventually removed, it is unlikely that the demolition will cause damage to the retained portion of the piers. The repair scope following the demolition works will address any damage that occurs to these elements.

10. Conclusion

This report provides a summary of the extensive studies and assessments undertaken on the Barwon Sewer Aqueduct over the past five years.

Technical aspects of the existing structure, including its current condition, structural behaviour and potential failure modes have informed significant safety limitations regarding any works in the vicinity of the structure. These have underpinned propping design attempts to meet the criteria of heritage permit P32806.

A full range of possible intervention categories were considered during design and assessment, many of which were deemed unfeasible at the start of the assessment period, due to the poor condition of the structure (concrete repair, cathodic protection, river span propping, do nothing).

Structural propping of the land spans was developed as the most promising intervention, however after significant design work and iterations to eliminate and mitigate safety risks, the most viable design options still resulted in the exposure of construction workers to residual safety risks above the SFAIRP threshold.

The conclusion was reached that the stated goals of heritage permit P32806 (partial demolition and conservation of the remaining structure) could not be safely or practically met whilst upholding duty of care responsibilities under OSHA, as detailed in Lovell Chen's Heritage Impact Statement.

Thus demolition of the entire aqueduct superstructure is now put forward as the sole remaining option available. Retention of pier bases and stairs, and potential opportunistic salvage of other components post-demolition offers some limited opportunity to retain part of the aqueduct fabric.

Martin Luoni
Associate Structural Engineer
Arup

Appendix A: Risk Workshop Residual Risk Tables

Spalling Risk Register

Risk ID	Project Activity	Risk Description	Inherent Consequence	Likelihood Description	Inherent Likelihood	Inherent Risk Rating	Proposed Controls	Residual Consequence	Residual Likelihood	Residual Risk Rating	Notes
R.1.1	Site Mobilisation & Construction Works	Spontaneous concrete spalling / detachment results in concrete striking a person causing: C.1 Debris Impact to Sensitive / Vulnerable Areas Leading to Extensive and/or Permanent Injury	Severe (C = 4)	Indicative of current condition of structure where spontaneous concrete spalling / detachment does occur at the aqueduct structure but would be unlikely to coincide with the time and location that works are taking place.	Unlikely B Very few or known instances requires multiple factors to occur	Medium (4B)	Refer Bow Tie and Controls Description Attached. Key primary controls are: - Enforced exclusion zone for non-critical personnel. - Pre-spalling/dislodgement of concrete at risk of falling. - Spall protection structures to catch falling debris. Secondary controls: - Pre-work inspections, spontaneous spall monitoring a stop-work procedures - PPE to sensitive areas (eyes, head). - Emergency response planning for person(s) struck by debris	Major (C = 3)	Rare A Event will only occur in exceptional circumstances	Insignificant (3A)	In this scenario the detached concrete strikes the structure while falling causing a larger quantity of fragments than generated by the act of spalling alone but these fragments are dispersed over a wider area. Reduction to "rare" based on use of exclusion measures (e.g. fencing) to prevent person(s) being exposed to the risk outside of working areas. Consequence reduced in C3 based on effectiveness of PPE
R.1.2	Site Mobilisation & Construction Works	Works induced concrete spalling / detachment results in concrete striking a person causing: C.1 Debris Impact to Sensitive / Vulnerable Areas Leading to Extensive and/or Permanent Injury	Severe (C = 4)	As above but works activities are more likely to create conditions for concrete detachment.	Possible C Event could occur at same time	High (1C)	Refer Bow Tie and Controls Description Attached. Key primary controls are: - Enforced exclusion zone for non-critical personnel. - Pre-spalling/dislodgement of concrete at risk of falling. - Spall protection structures to catch falling debris. Secondary controls: - Pre-work inspections, spontaneous spall monitoring a stop-work procedures - PPE to sensitive areas (eyes, head). - Emergency response planning for person(s) struck by debris.	Major (C = 3)	Unlikely B Very few or known instances requires multiple factors to occur	Low (3B)	Inherent likelihood increased relative to R.1.1 as both the works may increase likelihood of detachment and also the number of persons in the vicinity of the structure increases. Consequence reduced to C3 based on effectiveness of PPE
R.2.1	Site Mobilisation & Construction Works	Spontaneous concrete spalling / detachment results in concrete striking a person causing: C.2 Impact to Person(s) Leading to Single or Multiple deaths or Severe Permanent Disability	Extreme (C = 5)	While spontaneous concrete spalling is assessed as unlikely - to cause serious injuries and fatalities, the size of spalling required to cause serious injuries and fatalities (e.g. several kg) is lower likelihood (1A)	Unlikely B Very few or known instances requires multiple factors to occur	High (2B)	Refer Bow Tie and Controls Description Attached. Key primary controls are: - Enforced exclusion zone for non-critical personnel. - Pre-spalling/dislodgement of concrete at risk of falling. - Spall protection structures to catch falling debris. Secondary controls: - Pre-work inspections, spontaneous spall monitoring a stop-work procedures - PPE to sensitive areas (eyes, head). - Emergency response planning for person(s) struck by debris.	Severe (C = 4)	Rare A Event will only occur in exceptional circumstances	Low (4A)	In this scenario, the detached concrete remains largely intact and has a mass of several kg, which is sufficient to cause serious injuries and/or fatalities. Inherent likelihood is assessed as lower than for Risk ID R1.1 above, however the likelihood does not fall into the "rare" category. Reduction of residual risk to "rare" based on use of exclusion measures (e.g. fencing) to prevent person(s) being exposed to the risk outside of working areas. Proposed controls reduce the likelihood that a person is struck by a large fragment and PPE may reduce potential consequences. Outside working areas likelihood is assessed to reduce (i.e. exclude persons) but as disengagement activities may not have taken place and PPE reduce potential consequences but still result in serious injuries
R.2.2	Site Mobilisation & Construction Works	Works induced concrete spalling / detachment results in concrete striking a person causing: C.2 Impact to Person(s) Leading to Single or Multiple deaths or Severe Permanent Disability	Extreme (C = 5)	Works activities are more likely to create conditions for concrete detachment.	Possible C Event could occur at same time	Extreme (1C)	Refer Bow Tie and Controls Description Attached. Key primary controls are: - Enforced exclusion zone for non-critical personnel. - Pre-spalling/dislodgement of concrete at risk of falling. - Spall protection structures to catch falling debris. Secondary controls: - Pre-work inspections, spontaneous spall monitoring a stop-work procedures - PPE to sensitive areas (eyes, head). - Emergency response planning for person(s) struck by debris.	Severe (C = 4)	Unlikely B Very few or known instances requires multiple factors to occur	Medium (4B)	Inherent likelihood increased relative to R.2.1 as both the works may increase likelihood of detachment and also the number of persons in the vicinity of the structure increases. Proposed controls reduce the likelihood that a person is struck by a large fragment and PPE may reduce potential consequences. Within working areas likelihood is assessed to reduce (i.e. protection structures) but disengagement activities will deliberately create spall/dislodgement and the pattern of fall/impact with structure is complex to predict and hence inform the positioning of protective structures and PPE reduce potential consequences but still result in serious injuries.
R.3.1	Site Mobilisation & Construction Works	Spontaneous concrete spalling / detachment results in concrete striking a person causing: C.1 Minor Injury from Impact by Concrete Fragments	Moderate (C = 2)	Spontaneous concrete spalling / detachment does occur at the aqueduct structure but would be unlikely to coincide with the time and location that works are taking place.	Unlikely B Very few or known instances requires multiple factors to occur	Insignificant (2B)	Refer Bow Tie and Controls Description Attached. Key primary controls are: - Enforced exclusion zone for non-critical personnel. - Pre-spalling/dislodgement of concrete at risk of falling. - Spall protection structures to catch falling debris. Secondary controls: - Pre-work inspections, spontaneous spall monitoring a stop-work procedures - PPE to sensitive areas (eyes, head). - Emergency response planning for person(s) struck by debris.	Moderate (C = 2)	Rare A Event will only occur in exceptional circumstances	Insignificant (2A)	Reduction to "rare" based on use of exclusion measures (e.g. fencing) to prevent person(s) being exposed to the risk outside of working areas.
R.3.2	Site Mobilisation & Construction Works	Works induced concrete spalling / detachment results in concrete striking a person causing: C.3 Minor Injury from Impact by Concrete Fragments	Moderate (C = 2)	Works activities are more likely to create conditions for concrete detachment.	Possible C Event could occur at same time	Low (3C)	Refer Bow Tie and Controls Description Attached. Key primary controls are: - Enforced exclusion zone for non-critical personnel. - Pre-spalling/dislodgement of concrete at risk of falling. - Spall protection structures to catch falling debris. Secondary controls: - Pre-work inspections, spontaneous spall monitoring a stop-work procedures - PPE to sensitive areas (eyes, head). - Emergency response planning for person(s) struck by debris.	Moderate (C = 2)	Unlikely B Very few or known instances requires multiple factors to occur	Insignificant (2B)	Likelihood reduction based upon efficacy of spall reduction measures. Consequence remains as "Minor injuries".

Vertical Collapse Risk Register

Risk ID	Project Activity	Risk Description	Inherent Consequence	Likelihood Description	Inherent Likelihood	Inherent Risk Rating	Proposed Controls	Residual Consequence	Residual Likelihood	Residual Risk Rating	Notes
R 1.1.1	Construction Works	Additional Imposed Loads causing Vertical Structural Collapse During Construction resulting in: 1 Debris Impact to Sensitive / Vulnerable Areas Leading to Extensive and/or Permanent Injury or Illness (C = 4) 2 Crushing of Person(s) Leading to Single or Multiple Deaths or Severe Permanent Disability (C = 5) 3 Dust Inhalation Leading to Significant Injury or Illness (C = 3)	Extreme (C = 5)	Nature of proposed works does limit additional loading on the structure (most items intended to be placed below the structure) but some items will be placed on the structure (e.g. baskets). Without additional controls "event could occur at some time".	Possible C Event could occur at some time	Extreme (VC)	Refer Bow Tie and Controls Description Attached. Key primary controls are: - Enforced exclusion zone for non-critical personnel. - Engineering assessment and limits on additional loads. - Alternative load paths / temporary & permanent support structures. Secondary controls: - Engineer approved method statements - Structural monitoring and alarm systems - PPE	Severe (C = 4)	Unlikely B Event is not expected to occur	Medium (MB)	Consequence reduced based on exclusion zone reducing likelihood of crushing consequence. Likelihood reduction contingent on following method statement and administrative controls. Temporary structures may or may not be in place and hence partially effective.
R 1.1.2.1	Construction Works	Concrete Detachment via Works Activities causing Vertical Structural Collapse During Construction resulting in: 1 Debris Impact to Sensitive / Vulnerable Areas Leading to Extensive and/or Permanent Injury or Illness (C = 4) 2 Crushing of Person(s) Leading to Single or Multiple Deaths or Severe Permanent Disability (C = 5) 3 Dust Inhalation Leading to Significant Injury or Illness (C = 3)	Extreme (C = 5)	Concrete detachment should only occur where the concrete is already weakened and provides little contribution to current structural capacity. If concrete detachment gives rise to collapse modes such events would potentially already have occurred.	Unlikely B Event is not expected to occur	High (SB)	Refer Bow Tie and Controls Description Attached. Key primary controls are: - Enforced exclusion zone for non-critical personnel. - Alternative load paths / temporary & permanent support structures. - Pre-works condition survey & works restrictions Secondary controls: - Engineer approved method statements - Structural monitoring and alarm systems - PPE	Severe (C = 4)	Unlikely B Event is not expected to occur	Medium (MB)	Consequence reduced based on exclusion zone reducing likelihood of crushing consequence. Likelihood reduction contingent on following condition survey and administrative controls. However, not sufficient to reduce likelihood to "rare". Temporary structures may or may not be in place and hence partially effective.
R 1.1.2.2	BAU Condition	Environmental Deterioration of Concrete and/or Steel causing Vertical Structural Collapse resulting in: 1 Debris Impact to Sensitive / Vulnerable Areas Leading to Extensive and/or Permanent Injury or Illness (C = 4) 2 Crushing of Person(s) Leading to Single or Multiple Deaths or Severe Permanent Disability (C = 5) 3 Dust Inhalation Leading to Significant Injury or Illness (C = 3)	Extreme (C = 5)	If left unlimited, the structure would be expected to degrade to the extent where collapse would occur. However, the number of people or under the structure is typically low in BAU conditions reducing the likelihood of persons being impacted by a collapse.	Possible C Event could occur at some time	Extreme (VC)	Refer Bow Tie and Controls Description Attached. Key primary controls are: - Enforced exclusion zone for non-critical personnel. - Alternative load paths / temporary & permanent support structures. Secondary controls: - Engineer approved method statements - Structural monitoring and alarm systems - PPE	Extreme (C = 5)	Unlikely B Event is not expected to occur	High (SB)	This represents the fundamental risk assessment for the project as a whole. Noted that exclusion zone is less likely to be effective in BAU as regular attendance at site will not deter unauthorised access.
R 1.2.1	Demolition Works	Impact by Structure During Demolition causing Vertical Structural Collapse resulting in: 1 Debris Impact to Sensitive / Vulnerable Areas Leading to Extensive and/or Permanent Injury or Illness (C = 4) 2 Crushing of Person(s) Leading to Single or Multiple Deaths or Severe Permanent Disability (C = 5) 3 Dust Inhalation Leading to Significant Injury or Illness (C = 3)	Extreme (C = 5)	Given nature of structure (all elements being demolished at the same level) substantial impact during demolition is unlikely.	Unlikely B Event is not expected to occur	High (SB)	Refer Bow Tie and Controls Description Attached. Key primary controls are: - Enforced exclusion zone for non-critical personnel. - Alternative load paths / temporary & permanent support structures. - Demolition method statement. Secondary controls: - Structural monitoring and alarm systems - PPE	Severe (C = 4)	Unlikely B Event is not expected to occur	Medium (MB)	Consequence reduced based on exclusion zone reducing likelihood of crushing consequence. Likelihood reduction contingent on following condition survey and administrative controls. However, not sufficient to reduce likelihood to "rare". Temporary structures may or may not be in place and hence partially effective.
R 1.2.2	Site Mobilisation, Demolition & Construction Works	Vehicle Impact causing Vertical Structural Collapse resulting in: 1 Debris Impact to Sensitive / Vulnerable Areas Leading to Extensive and/or Permanent Injury or Illness (C = 4) 2 Crushing of Person(s) Leading to Single or Multiple Deaths or Severe Permanent Disability (C = 5) 3 Dust Inhalation Leading to Significant Injury or Illness (C = 3)	Extreme (C = 5)	Site is not located on a public roads, also proposed roadway is c.15m from existing structure (lower distance to cable anchorage and some specialist equipment e.g. piling rigs may approach within 2m).	Unlikely B Event is not expected to occur	High (SB)	Refer Bow Tie and Controls Description Attached. Key primary controls are: - Enforced exclusion zone for non-critical personnel and vehicles - Alternative load paths / temporary & permanent support structures. - Impact protection for vulnerable / exposed elements. Secondary controls: - Structural monitoring and alarm systems - PPE - Site policies (speed, drug & alcohol)	Severe (C = 4)	Unlikely B Event is not expected to occur	Medium (MB)	Current proposed controls will substantially reduce the likelihood of impact at ground level (appropriate barriers and exclusion zones). Activities proposed at height (e.g. approaching structure in baskets / suspended platforms / temporary structures) primarily rely on administrative controls (e.g. method statements and works policies) likelihood is assessed to reduce - however it remains "unlikely". Note that risk is not eliminated - incidents such as crane failure have occured in Victoria in the past few months. Consequence reduction is contingent on exclusion zone however persons in the vicinity (2m zone) may still be injured by debris.
R 1.2.3	Site Mobilisation, Demolition & Construction Works	Plant or Remedial / Temporary Structural Impact causing Vertical Structural Collapse resulting in: 1 Debris Impact to Sensitive / Vulnerable Areas Leading to Extensive and/or Permanent Injury or Illness (C = 4) 2 Crushing of Person(s) Leading to Single or Multiple Deaths or Severe Permanent Disability (C = 5) 3 Dust Inhalation Leading to Significant Injury or Illness (C = 3)	Extreme (C = 5)	Works activities take place either in suspended "baskets" or from ground below the structure which reduces the potential for substantial impact on the structure. However, in the absence of specific controls the scenario is considered Unlikely.	Unlikely B Event is not expected to occur	High (SB)	Refer Bow Tie and Controls Description Attached. Key primary controls are: - Enforced exclusion zone for non-critical personnel. - Alternative load paths / temporary & permanent support structures. - Construction method statement. Secondary controls: - Structural monitoring and alarm systems - PPE	Severe (C = 4)	Unlikely B Event is not expected to occur	Medium (MB)	Consequence reduced based on exclusion zone reducing likelihood of crushing consequence Likelihood somewhat reduced but controls are either administrative (method statement) or partial (temporary structures).
R1.1	Site Mobilisation & Construction Works	Overload or Impact During Construction resulting in: 4 Progressive (Longitudinal) Collapse of Structure	Extreme (C = 5)	This risk is contingent on a previously identified risk scenario occurring, principally a scenario that results in an out of balance loading condition. However, given that the event is contingent on previous risks it is assessed as unlikely, bordering on rare.	Unlikely B Event is not expected to occur	High (SB)	Refer Bow Tie and Controls Description Attached. Key primary controls are: - Alternative load paths / temporary & permanent support structures. - Construction / demolition method statement. Secondary controls: - Structural monitoring and alarm systems - PPE - Exclusion zones (along length of viaduct)	Severe (C = 4)	Unlikely B Event is not expected to occur	Medium (MB)	Consequence reduced based on exclusion zone reducing likelihood of crushing consequence. Likelihood somewhat reduced but controls are either administrative (method statement) or partial (temporary structures).

Risk ID	Project Activity	Risk Description	Inherent Consequence	Likelihood Description	Inherent Likelihood	Inherent Risk Rating	Proposed Controls	Residual Consequence	Residual Likelihood	Residual Risk Rating	Notes
R1.1.1.1	Site Mobilisation & Construction Works	Natural Event (e.g. high winds or seismic) causing Horizontal (Sideways) Structural Collapse During Construction resulting in: 1 Debris Impact to Sensitive / Vulnerable Areas Leading to Extensive and/or Permanent Injury or Illness (C = 4) 2 Crushing of Person(s) Leading to Single or Multiple Deaths or Severe Permanent Disability (C = 5) 3 Dust Inhalation Leading to Significant Injury or Illness (C = 3) 4 Fall from Height Leading to Single or Multiple Deaths or Severe Permanent Disability (C = 5)	Extreme (C = 5)	While structure is in a degraded state, it has not experienced collapse due to natural events to date. The expected works in-and-of themselves should not alter the exposure to natural events.	Rare A Event will only occur in exceptional circumstances	Medium (5A)	Refer Bow Tie and Controls Description Attached. Key primary controls: - Proposed temporary structural supports (trusses and cables). - Personnel exclusion zones. Secondary Controls include: - Structural monitoring, alerts & evacuation.	Extreme (C = 5)	Rare A Event will only occur in exceptional circumstances	Medium (5A)	Both likelihood and consequence largely unchanged by controls (structure is currently subject to high winds and recent seismic events noted in workshop).
R.1.1.1.2	Site Mobilisation & Construction Works	Accelerated weakening of structure during construction works causing Horizontal (Sideways) Structural Collapse During Construction resulting in: 1 Debris Impact to Sensitive / Vulnerable Areas Leading to Extensive and/or Permanent Injury or Illness (C = 4) 2 Crushing of Person(s) Leading to Single or Multiple Deaths or Severe Permanent Disability (C = 5) 3 Dust Inhalation Leading to Significant Injury or Illness (C = 3). 4 Fall from Height Leading to Single or Multiple Deaths or Severe Permanent Disability (C = 5)	Extreme (C = 5)	Accelerated weakening could occur however to result in the collapse mode described requires multiple factors to occur.	Rare A Event will only occur in exceptional circumstances	Medium (5A)	Refer Bow Tie and Controls Description Attached. Key primary controls: - Proposed temporary structural supports (trusses and cables). - Personnel exclusion zones. Secondary Controls include: - Structural monitoring, alerts & evacuation. - Engineer method statements and associated limitations.	Extreme (C = 5)	Rare A Event will only occur in exceptional circumstances	Medium (5A)	Some factors potentially increase likelihood (e.g. concrete disengagement) however temporary works strategy is intended to provide supplemental structural stability to reduce likelihood of collapse.
R.1.1.1.3	Site Mobilisation & Construction Works	Addition of new materials / equipment load causing Horizontal (Sideways) Structural Collapse During Construction resulting in: 1 Debris Impact to Sensitive / Vulnerable Areas Leading to Extensive and/or Permanent Injury or Illness (C = 4) 2 Crushing of Person(s) Leading to Single or Multiple Deaths or Severe Permanent Disability (C = 5) 3 Dust Inhalation Leading to Significant Injury or Illness (C = 3) 4 Fall from Height Leading to Single or Multiple Deaths or Severe Permanent Disability (C = 5)	Extreme (C = 5)	Unintentional overload could occur however to result in the collapse mode described requires multiple factors to occur.	Rare A Event will only occur in exceptional circumstances	Medium (5A)	Refer Bow Tie and Controls Description Attached. Key primary controls: Proposed temporary structural supports (trusses and cables). - Personnel exclusion zones. Secondary Controls include: - Structural monitoring, alerts & evacuation. - Engineer method statements and associated limitations.	Extreme (C = 5)	Rare A Event will only occur in exceptional circumstances	Medium (5A)	Proposed works method does not involve the intentional placement of supplemental loads on the piers. Potential unintensional impact addressed below.
R.1.1.2	Site Mobilisation & Construction Works	Vehicle or Equipment Impact causing Horizontal (Sideways) Structural Collapse During Construction resulting in: 1 Debris Impact to Sensitive / Vulnerable Areas Leading to Extensive and/or Permanent Injury or Illness (C = 4) 2 Crushing of Person(s) Leading to Single or Multiple Deaths or Severe Permanent Disability (C = 5) 3 Dust Inhalation Leading to Significant Injury or Illness (C = 3) 4 Fall from Height Leading to Single or Multiple Deaths or Severe Permanent Disability (C = 5)	Extreme (C = 5)	Both site access and proposed works methods (work platforms and hoist cages) together with exposed nature of site raise likelihood that unintentional impact could occur. Risk also possesses shorter chain of causation. However this style of impact is more likely to lead to a vertical collpase mode.	Rare A Event will only occur in exceptional circumstances	Medium (5A)	Refer Bow Tie and Controls Description Attached. Key primary controls are: Enforced exclusion zone for non-critical personnel and vehicles. Alternative load paths / temporary & permanent support structures. - Impact protection for vulnerable / exposed elements. Secondary controls: - Structural monitoring and alarm systems - PPE - Site policies (speed, drug & alcohol).	Extreme (C = 5)	Rare A Event will only occur in exceptional circumstances	Medium (5A)	Current proposed controls will substantially reduce the likelihood of impact at ground level (appropriate barriers and exclusion zones). Activities proposed at height (e.g. approaching structure in baskets / suspended platforms / temporary structures) primarily rely on administrative controls (e.g. method statements and works policies) likelihood is assessed to reduce - however it remains "unlikely". Note that risk is not eliminated - incidents such as crane failure have occured in Victoria in the past few months. Owing to horizontal collapse mode and potential influence area - risk of fatalities remains therefore consequence remains extreme.
R.1.1.3.2	Site Mobilisation & Construction Works	H.1.1.3.2 Vibration / Compaction of Soil due to Construction Activities causing Horizontal (Sideways) Structural Collapse During Construction resulting in: 1 Debris Impact to Sensitive / Vulnerable Areas Leading to Extensive and/or Permanent Injury or Illness (C = 4) 2 Crushing of Person(s) Leading to Single or Multiple Deaths or Severe Permanent Disability (C = 5) 3 Dust Inhalation Leading to Significant Injury or Illness (C = 3) 4 Fall from Height Leading to Single or Multiple Deaths or Severe Permanent Disability (C = 5)	Extreme (C = 5)	Given age of asset, unanticipated changes in ground conditions are unlikely, however proposed works could occur owing to construction works. Collapse mode still has multiple stages in chain of causation.	Unlikely B Very few or known instances requires multiple factors to occur	High (5B)	Refer Bow Tie and Controls Description Attached. Key primary controls: - Proposed temporary structural supports (trusses and cables). - Personnel exclusion zones. - Vibration Monitoring & Limits. Secondary Controls include: - Structural monitoring, alerts & evacuation. - Engineer method statements and associated limitations.	Extreme (C = 5)	Rare A Event will only occur in exceptional circumstances	Medium (5A)	Proposed vibration monitoring and associated controls should minimise / eliminate the risks associated with changing ground conditions.

Appendix B: 2024 Arup Condition Report

Barwon Aqueduct Condition Report #1

To	Laura Shelley, Barwon Water Cat McConkey, Barwon Water
Date	5 August 2024
Copies	Joseph Correnza, Arup Jorja Zanotto, Arup
Reference number	280457

Subject	**Barwon Sewer Aqueduct** **Condition Report #1**

1. Executive Summary

This document outlines Arup's condition report for the Ovoid Sewer Aqueduct over the Barwon River at Breakwater. The Aqueduct is a reinforced concrete truss bridge in an advanced state of deterioration and decay resulting from carbonation and material failure of the concrete cover and progressive rusting of the reinforcing steel structure[1].

This report contains visual observations from comparative condition assessments carried out on three separate datasets obtained between 2022-2024. It is the first such condition report undertaken for the structure.

We find that some visual degradation of the structure has occurred between the compared datasets, including new spalling observed in some members. Whilst the majority of members remain unchanged in their outwardly visible condition, results do show that ongoing degradation of the structure is occurring and is likely to continue on a similar basis into the future. It is not possible to predict timing of future failures with any degree of accuracy, but ongoing degradation means that delays in commencement of the propping construction works will increase the risk of failures prior to completion of the propping works.

The condition inspections and reporting within this document are provided in accordance with Heritage Victoria permit ref P32806, Clause 14(d). We note this condition report is the initial instance of the expected ongoing reporting outlined within the permit, which calls for 6-monthly ongoing visual inspections.

[1] HIMP Part 1, Page 5

2. Introduction

The Aqueduct is a reinforced concrete truss bridge in an advanced state of deterioration and decay resulting from carbonation and material failure of the concrete cover and progressive rusting of the reinforcing steel structure. In 2020, Heritage Victoria issued a permit (P32806) for the partial demolition of four of the Aqueduct's original fourteen spans, in combination with conservation works (structural propping) and other conditions. After the completion of the permitted works, the balance of the structure will be retained as a managed ruin within the future *Porronggitj Karrong* cultural and community precinct.

This condition report has been undertaken prior to any of the new propping or demolition works being carried out, with all 14 spans of the structure being intact at the time of observation, and no obvious signs of member failure being evident in the structure. The structure is self-supporting except for Span 14 which is already propped with steelwork (dating from 1991).

3. Site Captures and Inputs

This condition report represents a comparative study of the structural condition at three points in time, based upon separate visual datasets as follows:

3.1 2024/07/10 Site Inspection - Arup

Arup structural engineers undertook a site inspection on 10 July 2024 (Martin Luoni and Kimberley Ng). A Matterport Pro3 3D camera unit was used to capture the entire extent of the accessible structure and produce a suite of 3D Matterport models, which are accessible through online portal – refer links:

SE: https://my.matterport.com/models/XRyJdfZLopY?section=media
SW: https://my.matterport.com/models/MZChVddmMkG?section=media
NE: https://my.matterport.com/models/npPeRkru1i1?section=media
NW: https://my.matterport.com/models/pVZBcq711tK?section=media

A digital DSLR camera with zoom lens was also used to capture detailed photographs of heavily degraded areas where visible. Weather conditions during the inspection were fine, with light winds and temperatures approximately 10-14 degrees Celsius.

The site inspections were undertaken from ground level, following the exclusion zone limits with people always remaining 12m from the structure. Areas were captured in the following sequence, with all observations made travelling north-south.

1. South side – East
2. South side- West
3. North side – East
4. North side – West

Piers 10 and 11 (Goat Island) were unable to be captured due to access constraints. Additionally, limitations of the ground-based survey meant that the top sides of elements could not be viewed. Degraded areas on the rear faces of members are typically not visible due to the angle of viewing.

3.2 2023/12/12 Drone LIDAR - Diospatial

Diospatial (engaged via Arup) undertook a drone-based reality capture of the structure on 12 December 2023. A drone mounted YS Surveyor Ultra unit was used to capture the structure and produce a LiDAR model of the structure.

This model is hosted on the online portal Pointerra at the below link: (password *1915Wobble)*

https://app.pointerra.io/users/guest_login/?token=pc_cnwGPo7vdwry7MZcpiSzeQ

The LiDAR model is a 3d photographic surface of high visual clarity and allows for good desktop review and comparison to other datasets, with the ability to review multiple angles of members. The entire extent of the structure was captured in the LiDAR model; however, the underside of elements is not resolved in all areas, due to the high angle of the drone. Additionally, heavy vegetation on Goat Island meant some members in that area were unable to be captured.

3.3 2021/2022 Archival Photography - Glasshouse

Archival photography was undertaken by Glasshouse Creative Media, for the purpose of heritage record of the structure. The archival photography was provided to Arup by Lovell Chen on 27 June 2024 and used to inform condition reporting at that time. We understand the photography was captured over two separate site works periods:

2021: Jun 28 – July 9: Initial drone photography – elevation images used principally for condition reporting

2022: March 30/31: Subsequent static ground-based photography using DSLR

We have used assets from the photographic record where possible to compare back to the conditions at 2021/2022. The primary reference photographs set used were the 10m elevation drone shots.

4. Condition Reporting – Intent and Methodology

The primary purpose of this condition report is to prepare a baseline picture of the general structural condition of the structure and identify changes in condition between the datasets. We have focussed on key structural elements of the structure when considering review of members.

The methodology broadly involved the following steps:

1. Define individual members of the structure – refer Figure 1 on next page for key. A total of 2674 members were identified for the reporting. The highest risk members for structural failure were the primary focus of the review, particularly around the trusses and piers, noting the lower redundancy of these elements against failure. Pipes, walkway and walkway support beams within the truss extents were not included in the condition reporting as these elements were not deemed as critical for the ongoing load carrying capability of the structure.

2. Create a ranking key for identification of individual members of the structure (1-5) – refer Figure 2 for a full table and reference images of each ranking. The condition rankings are as follows:

   (0. Unrated due to lack of visual information)
   1. No visible deterioration, or hairline cracking only. No visible loss of material.
   2. Open cracks present, no visible loss of material
   3. Localised spalling to one or two areas of member
   4. Widespread spalling to member, cover concrete lost. Bars visible, core concrete intact
   5. Widespread loss of cover concrete. Loss of concrete around bar. Visible degradation of reinforcement present
   6. Visible member failure or complete loss

3. Assess each member condition based upon the visual information available and provide a ranking on the 1-6 scale. Note any obvious past remedial works to the member, such as shotcrete repairs.

4. For heavily degraded members where reinforcement is visible (category 5 and above), obtain detailed visual reference (photo or screen clip) and compare side by side to identify any changes in the condition. Map heavily degraded members on a visual (long section) of the structure.

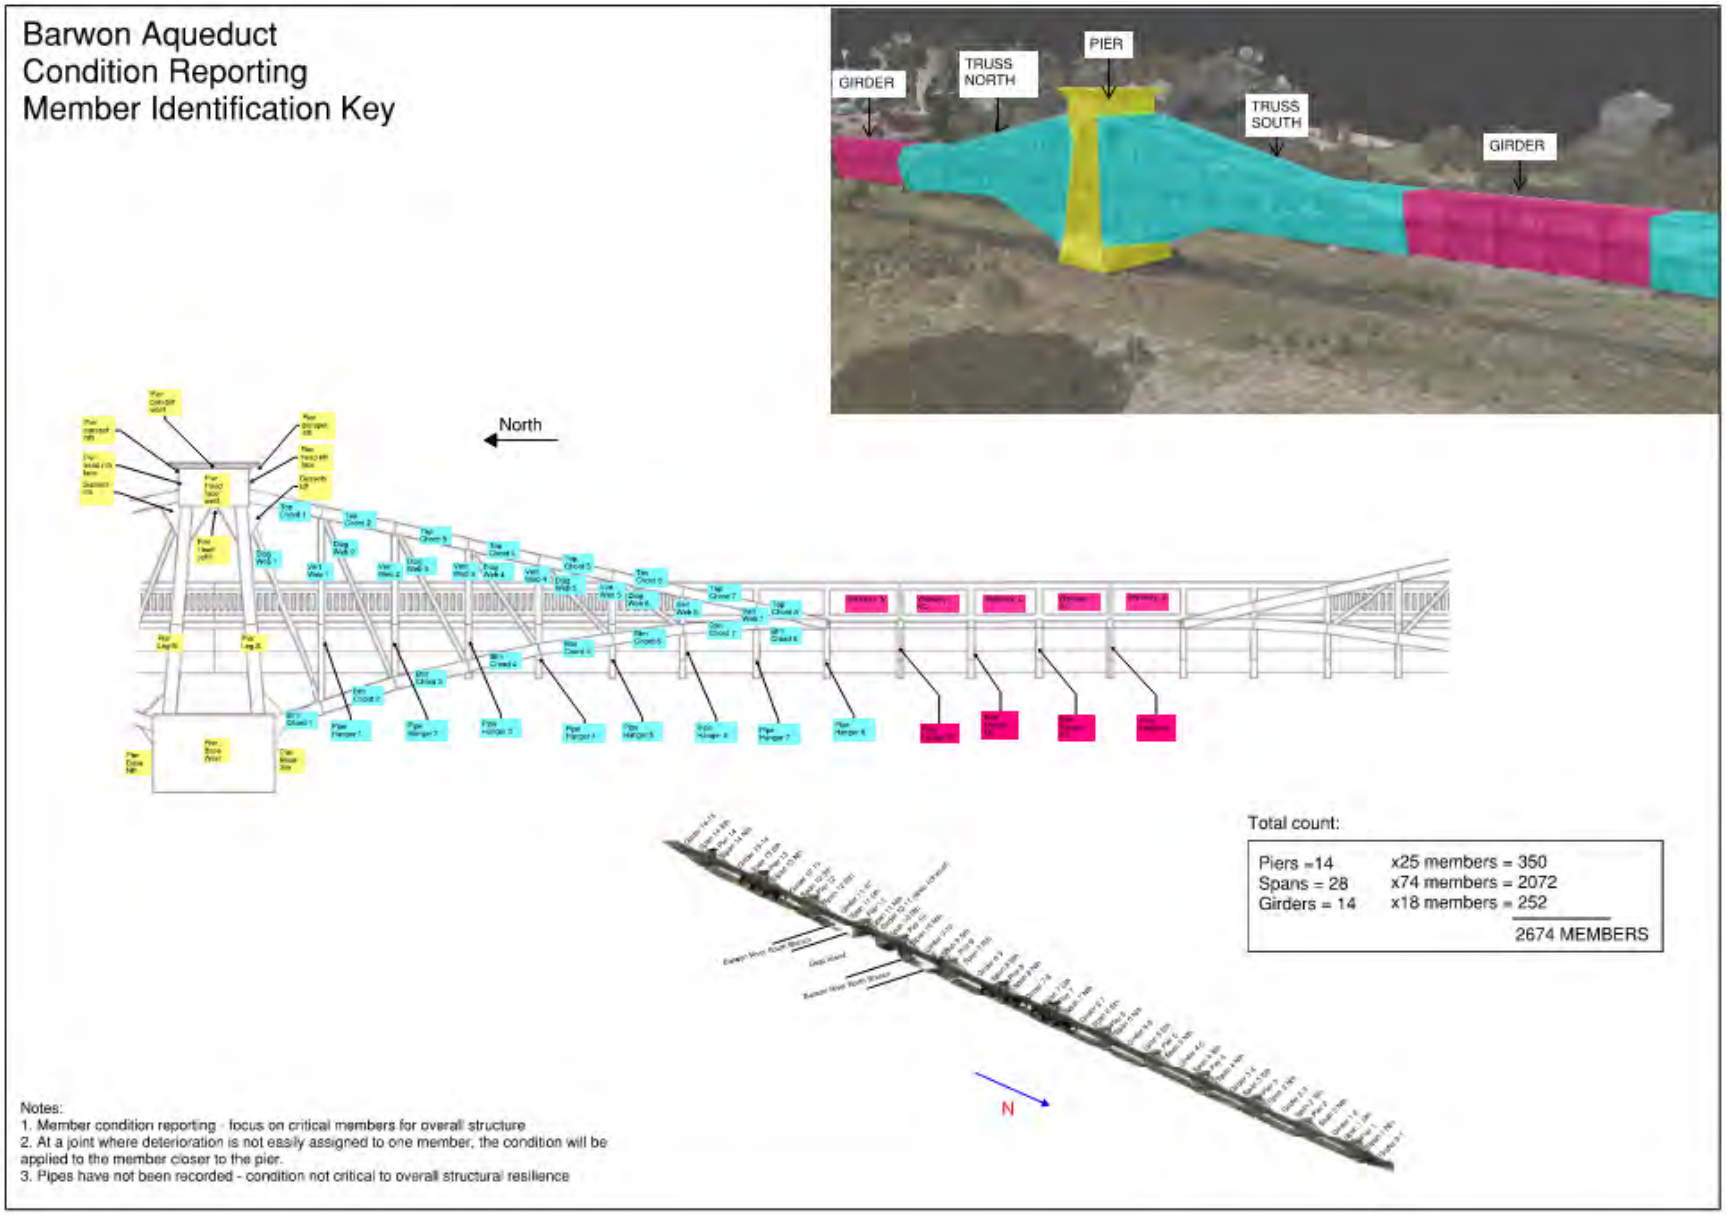

Figure 1 Member Identification Key

Barwon Aqueduct Condition Reporting - Member Rating Key

Rating 0: is for members where the member cannot be examined because either
- no data was collected
- the data is obscured by shadows/lack of data (for Point Cloud) OR
- vegetation obscures the member

1	2	3	4	5	6
Cracking hairline only, or not present No visible loss of material	Open cracks present No loss of material	Localised spalling to one or two areas of member.	Widespread spalling to member Cover concrete lost Bars visible over large part of member, but core concrete intact	Widespread loss of cover concrete Loss of concrete around bar Visible degradation of reinforcement present	Complete member loss / deformation
					No examples currently. Visual evidence includes : Clearly visible deformation of member. Detachment of member from structure Note that this category only applies to visibly deformed members.

Figure 2 Member Rating Key

5. Deterioration – Mechanisms and Visual Cues

Deterioration of the concrete structure is due primarily to carbonation of the concrete where the alkaline matrix of the concrete is lost, thus making the internal reinforcement susceptible to rusting. The typical sequence of events in the deterioration of a particular element is illustrated in the series of steps in Figure 3.

Previous engineering reports have discussed at length the deterioration processes on the aqueduct structure, along with measurements of the cover and carbonation depths in various locations. Findings have shown that carbonation depth in the truss members typically exceeds the depth to reinforcement, and that carbonation is the primary mechanism contributing to the structure's deterioration (Taywood Maunsell, 1990).

Cross Section	Visual	Condition Ranking
 Original cross section Hoop reinforcement Longitudinal (main) reinforcement	No visible sign of decay	1
 Carbonation Carbonated concrete - carbonation progresses internally, starting from surface of member. Once carbonation passes reinforcement depth, rusting of bars can occur.	No visible sign of decay	1
 Rusting of bar Rusting of bar increases volume (iron oxide) and creates expansionary pressure in concrete. Expansion pressure causes cracking in concrete - visible on exterior as longitudinal cracks typical.		2
 Spalling Cracked cover concrete detaches, exposing rusty reinforcing bars to view		3 , 4
 Loss of Cover Spalling continues, with cover concrete lost.		3 , 4
 Loss of hoop reinforcing Hoop reinforcing (small diameter) rusts through, causing breakage of hoop		5
 Main bar Loss Main bars (larger diameter) rust through, and/or detach from remaining core of concrete.		5+
Member structural failure follows after critical amount of main bar loss, critical loss of concrete core, buckling of main bars or loss of bar anchorage		5+

Figure 3 Deterioration Steps

6. Condition Results

6.1 Raw Data

Refer appended table Appendix A for full grading of all members in the structure.

A summary of members by category is provided in Table 1 and shows the number of structural elements in each category. Note that the number of unrated '0' members in each dataset represents the number of members unable to be seen in the review. The '0' count is different in each dataset as it is dependent on the extent of visual access. This demonstrates the relative lack of access to certain members, either due to limitations of ground-based review (Goat Island and river spans inaccessible) or other limitations (e.g. drone survey blocked by vegetation on Goat Island).

The raw data is shown in Table 1 for completeness – noting that for all subsequent comparison metrics in the remainder of this report, any members with a '0' rating were removed from datasets before providing comparison statistics, so that clear measurements of change could be made by comparing a like for like set of data points.

Table 1 Raw Data - Member Ratings

Rating	Glasshouse 03/2022	Pointerra Point Cloud 12/2023	Matterport 07/2024
0	0	0	0
5	199	206	191
4	402	421	369
3	396	423	355
2	510	478	407
1	1085	1024	801
0 (unrated)	82	122	551
Total assessed	2592	2552	2123
Total members	2674	2674	2674

6.2 Comparison Data – Overall Results

When directly comparing members between the three datasets, (i.e. removing unrated '0' members if they exist in any of the datasets), a total of **2083** common members were able to be used for direct comparison. Refer Table 2 for the results and the ratings of each type.

Table 2 Comparison Data - Available Datapoints

Rating	Glasshouse 03/2022		Pointerra Point Cloud 12/2023		Matterport 07/2024	
5	170	8.16%	183	8.79%	184	8.83%
4	347	16.7%	362	17.4%	366	17.6%
3	328	15.7%	346	16.6%	346	16.6%
2	406	19.5%	389	18.7%	401	19.3%
1	832	39.9%	803	38.6%	786	37.7%
Total	**2083**	**100%**	**2083**	**100%**	**2083**	**100%**

More detailed side by side comparisons were undertaken for the 2022-2023 and 2023-2024 result sets. Note that due to visual limitations around resolution of the Matterport data, some finer details associated with cracking were difficult to interpret accurately. (For future ground-based surveys, high resolution photos shall be taken to supplement the Matterport captures.)

The Table 3 result comparison below between 2022-2023 (approx. 1 year period) below shows additional visible degradation occurred in 75 members, or approximately 4 % of the total population. Of the members showing degradation, 45 members degraded by a single category whilst 30 members degraded by two or more categories.

4x new category 5 members were identified over the period.

Table 3 Comparison Results – Member Rating 2022-2023

Glasshouse 03/2022 - Member Category		Pointerra Point Cloud 12/2023 - Member Category	Number of Elements	% of total
1	to	1	803	39%
1	to	2	13	1%
1	to	3	12	1%
1	to	4	3	0%
1	to	5	1	0%
2	to	2	376	18%
2	to	3	18	1%
2	to	4	6	0%
2	to	5	6	0%
3	to	3	316	15%
3	to	4	10	0%
3	to	5	2	0%
4	to	4	343	16%
4	to	5	4	0%
5	to	5	170	8%
Total members unchanged			**2008**	**96%**
Total members degraded			**75**	**4%**
Total members overall			**2083**	**100%**

The Table 4 result comparison below between 2023-2024 (approx. 6 month period) shows additional degradation occurred in 26 members, or approximately 1% of the total population. Of the members showing degradation, 24 members degraded by a single category whilst 2 members degraded by two or more categories.

1x new category 5 member was found over the period.

Table 4 Comparison Results - Member Rating 2023-2024

Pointerra Point Cloud 12/2023 - Member Category		Matterport 07/2024 - Member Category	Number of Elements	% of total
1	to	1	786	38%
1	to	2	16	1%
1	to	3	1	0%
1	to	4	0	0%

4	to	5	1	0%
5	to	5	183	9%
Total members unchanged			**2057**	**99%**
Total members degraded			**26**	**1%**
Total members overall			**2083**	**100%**

6.3 Comparison Data – By Structural Zone

The comparison data was also compared based on span/pier/girder structural zones, to illustrate the relative distribution of member degradation and level of degradation across the structure. Refer Page 5 for graphical definition of the structural zones.

Note that some zones (Span 9-12) had insufficient datapoints available (due to lack of access) to allow a meaningful comparison to be undertaken, so were omitted from results.

The zone score is provided as a measure of relative degradation across the zone and is shown on a rating scale between 0 and 1, to provide a comparative condition across different zones of the structure. (Note that when comparing results, zones should only be compared to other zones of the same type, as the zone types have been normalised as a group.)

The zone rating is calculated with the formula below, with the resulting rating then being normalised into a 0-1 scale for the zone type. Thus when reading the results table, the most degraded zone of each type is rated as 1.0, and the least degraded zone is rated as 0.0.

$$Zone\ rating = \left(\frac{\sum member\ category\ ratings}{Total\ member\ count}\right)$$

Table 5 shows the pattern of span (truss) zones degradation across the structure. A higher level of degradation is seen around Span 3 than other spans. We note the spans around the demolition cut points (Span 8 and Span 13) are the least degraded of all spans. A temporal pattern of increasing degradation across the datasets is illustrated in most spans.

Table 5 Condition Comparison by Zone - Spans

Span 14 Sth	62	0.52	62	0.52	62	0.52

Table 6 shows the pattern of pier zones degradation. Piers are generally more uniformly degraded than trusses typically, but again Pier 3-4 show the highest level of degradation. (Noting that most of the analysed members in the pier are concentrated around faces of the the pier head, which is not a structurally critical element.)

Table 6 Condition Comparison by Zone - Piers

	Glasshouse 03/2022		Pointerra Point Cloud 12/2023		Matterport 07/2024	
Zone	Number of Members Analysed	Overall Rating	Number of Members Analysed	Overall Rating	Number of Members Analysed	Overall Rating

Table 7 shows the pattern of girder zones degradation. Again, girders are more uniformly degraded than trusses typically across the structure and show slight increases in temporal degradation across the three datasets. We also note that girders are typically much less degraded than trusses and have a higher degree of redundancy.

Table 7 Condition Comparison by Zone - Girders

	Glasshouse 03/2022		Pointerra Point Cloud 12/2023		Matterport 07/2024

6.4 Results Discussion

The general results show that approximately 8.83% of the compared structural members are in very poor condition (Category 5) in 2024, increasing from 8.16% in 2022. We have provided a graphical summary (refer Figure 6) to illustrate the distribution of Category 5 members occurrence within the structure. Please see over for the summary, noting the concentration of heavily degraded members in the Span 3-4 area. This correlates with the results in Table 5.

As discussed in previous documents, whilst general conclusions can be drawn from the condition results, it is not possible to predict future failures with any degree of accuracy, in terms of timing of eventual structural failures. This is due to the following reasons:

1. Presence of additional unseen degradation in the member additional to what can be seen
2. Possibility of load redistribution through the structure, with load bypassing failed members
3. Effectiveness of reinforcement anchorage in the structure.

6.5 Category 5 Members - Detailed Review

Members of the structure that are in the worst condition are classed as Category 5. There are currently **184** Category 5 members as identified in the latest dataset.

The breakdown of Category 5 members per member type is shown in Table 8 below across the datasets. The Category 5 members are primarily truss members, with bottom chords, top chords and vertical web members making up most of the Category 5 heavily degraded dataset. The vertical webs have the highest level of relative degradation as a population, with approximately 19% of all vertical webs being at Category 5. This is likely due to the small cross section size of this member type, and the extensive ligatures resulting in more expansion forces which leads to spalling of cover concrete.

Table 8 Category 5 members split out by member type

		Glasshouse 03/2022		Pointerra Point Cloud 12/2023		Matterport 07/2024	
Element Type	Total Number of Members	Number of Category 5 members	Percent of Total at Category 5	Number of Category 5 members	Percent of Total at Category 5	Number of Category 5 members	Percent of Total at Category 5
Walkway beam	109	4	4%	4	4%	4	4%

Gussets	46	1	2%	1	2%	1	2%
Pier base	29	2	7%	2	7%	2	7%
SUM	**2083**	**170**		**183**		**184**	

The category 5 members are of most interest in condition reporting, as they are the most likely points for future failure initiation. We note that pier members are typically in better condition than the trusses – the pier members also have a relatively higher capacity for degradation based upon their larger cross sectional size. The most severely degraded members are in the trusses, both chords and vertical webs.

Some defects observed in the Category 5 members include the below (in order of increasing severity):

- Spalling of cover concrete, sometimes on all faces of the member

- Loss of confining stirrups/ligatures. The confining wire ligatures have been lost in several locations, exposing the main bars to potential buckling and accelerated corrosion. This is more critical in compression members (bottom chords, vertical webs) than tension members.

- In approximately 13x locations throughout the truss top and bottom chord of the bridge, main bar ends are visible and, in some cases, have detached from the core concrete. The bars appear to be splice points in the original structure. Bar ends that are visible are not anchored in the concrete matrix, and thus will not develop tension in the bar at the as-designed location. The exact effect of the development loss is difficult to quantify based upon visual review only, but is expected to have a significant effect on the load carrying capacity of these members and is thus a likely point of future failure. Refer Figure 4 for example.

Figure 4 Example of reinforcement splice degradation (member ref 598)

- Buckled main reinforcement - mainly in the thin vertical webs. This is evident where the reinforcing bars are no longer straight and have pulled away from the concrete core (typically coupled with loss of ligatures). Again, this effect has a significant effect on the load carrying capacity of these members. Refer Figure 5 for example.

Figure 5 Example of main bar buckling (Member Ref 1032) – daylight visible between bar and core concrete

Refer Figure 6 over for summary of Category 5 members on the structure, and Appendix B for full table of the Category 5 members. Where available, photos and/or point cloud images have been included and visually assessed side by side to determine any obvious signs of additional distress or further degradation. Isolated areas of additional spalling were identified in some of the Category 5 members (refer Appendix C), but no additional outward sign of increased distress in the members.

We note that as yet, no confirmed failures or significant member deformations (Category 6) have currently been recorded in the structure. Whilst heavily degraded members are likely to have lost some of their structural capacity, the imposed load is either still being taken by the member or being redistributed to adjacent members, thus avoiding visible signs of failure.

Figure 6 Summary of Category 5 members (2024)

7. Limitations of Condition Reporting

Visual inspection of the structure is limited to viewing the external surfaces of members, and therefore requires a degree of interpretation to understand the internal condition of the structure. Additionally, deterioration is a highly localised phenomenon, with different parts of the structure affected to varying degrees, as demonstrated in inspection records.

Finally, whilst drawings are available for the original structure, there are many members of the structure which have been remediated in the past, likely with additional reinforcement added. These remediations do not have documentation available, thus it is not possible to ascertain the exact construction details of the structure.

8. Conclusion

We trust the condition reporting herein provides a summary of the current condition of the structure. If there are any queries please don't hesitate to contact us.

Under the conditions of the Heritage Permit, we understand that condition inspection and reporting will be undertaken every 6 months in the first 5 years. This initial report can be used as a basis to inform future inspections and reporting.
